第1章

金鱼Scheme简介

金鱼Scheme，又称Goldfish Scheme，是三鲤网络发起的Scheme解释器实现。

金鱼Scheme解释器具有以下特性：

- 兼容R7RS small标准
- 提供类似Python的标准库
- 小巧且快速

1.1 背景

金鱼Scheme创建之初的目的是为了服务墨干理工套件及其商业版Liii STEM。

墨干一开始使用的是S7 Scheme，然而S7 Scheme并不严格遵循R7RS small标准，也没有提供常见的SRFI实现。故而我们决定在S7 Scheme的基础上，发布金鱼Scheme，更加严格地遵循R7RS small标准，并提供常见的SRFI实现作为金鱼Scheme的内置标准库。另外，无论是R7RS small还是SRFI都没有提供同时兼容macOS, GNU/Linux和Windows的类似于Python的os模块的标准库，故而我们模仿了Python的os模块，实现金鱼的内置标准库(`liii os`)，以提供`listdir`、`mkdir`等常见功能。

1.2 文学编程

金鱼Scheme最初的三位作者是沈达、刘念和Yansong Li，项目立项时就是采用文学编程的方式实现金鱼Scheme的Scheme部分。

一开始，我们的文学编程文档`Goldfish.tmu`是不开源的，我们只开源了金鱼Scheme的代码，其中代码是几乎没有任何注释的，因为我们在文学编程文档中的代码块之外会撰写注释。后来来自Emacs China社区的StarSugar开始向金鱼Scheme项目贡献代码，于是我们决定将金鱼Scheme的文学编程文档`Goldfish.tmu`也开源出来，整个项目以开源的方式推进。

从金鱼Scheme V17.10.8开始，我们确定了金鱼Scheme的文学编程文档的许可证为**知识共享署名-相同方式共享4.0国际许可协议**。

本文档是采用中文编写的。在2024年，开源软件项目的文档采用中文编写并不是主流。首先，金鱼Scheme项目的前三位作者的母语都是中文，采用母语作为文档的语言是自然而然的；其次，在大模型时代，计算机辅助翻译已经非常成熟且廉价，我们相信中文文档不会是金鱼Scheme走向世界的阻碍。

1.3 许可证

本文档采用文学编程方式编写，金鱼Scheme相关的所有代码几乎都包含在本文档中。本文档的许可证分为代码和文档两部分，其中代码部分采用Apache许可证，相关信息在每一个源代码文件的头部都会显式声明，未显式声明的源代码默认采用Apache许可证；其中文档部分采用**知识共享署名-相同方式共享4.0国际许可协议**授权。您可以自由地分享、修改本作品，只要您遵循以下条件：

署名。您必须给出适当的署名，提供作品的链接，并指明是否有任何变更。您可以以任何合理的方式做这些事，但不得以任何方式暗示许可人赞同您或您的使用。

相同方式共享. 如果您再混合、转换或基于本作品创作，您必须以相同的许可协议发布其成果。

金鱼Scheme是浙江三鲤网络科技有限公司发起的开源项目，我们在分发源代码时，版权信息统一采用The Goldfish Scheme Authors作为金鱼Scheme的作者。那么谁是The Goldfish Scheme Authors呢？这些信息我们会在金鱼Scheme的仓库的根目录下的AUTHORS文件中维护：

AUTHORS

```
# The original authors of the SRFI reference IMPL are kept in individual files
# This AUTHORS file is for The Goldfish Scheme Authors.
```

```
#
```

```
# Names should be added to this file like so:
```

```
# Name or Organization <email address>
```

```
Liii Network Inc. <*@liii.pro>
```

```
沈达 <da@liii.pro>
```

```
刘念 <nian@liii.pro>
```

```
Yansong Li <haggittli@gmail.com>
```

```
Leiyu He <heleiyu1231@gmail.com>
```

```
Duolei Wang <duolei.wang@gmail.com>
```

```
Yingyao Zhou <yingyaozhou51@gmail.com>
```

我们会联系金鱼Scheme的贡献者，更新AUTHORS文件。金鱼Scheme的贡献者并不一定在这个文件中，有可能我们没有及时更新，也有可能相关贡献者希望保持匿名。

1.4 相关机构

支持金鱼Scheme的相关机构如下所示：

- 浙江三鲤网络科技有限公司
- 中国科学技术大学-德清阿尔法创新研究院

第 2 章

boot.scm

S7 Scheme默认并不遵循R7RS，在启动S7 Scheme之后，我们需要做的第一件事就是加载`boot.scm`，实现R7RS的`define-library`和`import`。

R7RS 索引

```
goldfish/scheme/boot.scm 1 ▽
(define (file-exists? path)
  (if (string? path)
      (if (not (g_access path 0)) ; F_OK
          #f
          (if (g_access path 4) ; R_OK
              #t
              (error 'permission-error (string-append "No permission: " path)))
          (error 'type-error "(file-exists? path): path should be string"))))
```

R7RS 索引

goldfish/scheme/boot.scm ▾ 2 ▾

```
(define (delete-file path)
  (if (not (string? path))
      (error 'type-error "(delete-file path): path should be string")
      (if (not (file-exists? path))
          (error 'read-error (string-append path " does not exist"))
          (g-delete-file path))))
```

R7RS 索引

goldfish/scheme/boot.scm ▾ 3 ▾

```
; 0-clause BSD
; Adapted from S7 Scheme's r7rs.scm
(define-macro (define-library libname . body) ; |(lib name)| -> environment
  '(define ,(symbol (object->string libname))
    (with-let (sublet (unlet)
                      (cons 'import import)
                      (cons '*export* ())
                      (cons 'export (define-macro ,(gensym) . names)
                            '(set! *export* (append ',names *export*)))))

                  (symbol->value sym))))))
        libs))))
```

第 3 章

(liii base)

Goldfish Scheme解释器默认会加载

(liii base)由以下函数库组成：

(scheme base). 由R7RS定义的Scheme基础函数库

(srfi srfi-2). 由SRFI-2定义的and-let*

(srfi srfi-8). 由SRFI-8定义的receive

(liii base). 三鲤扩展函数和S7内置的非R7RS函数，例如display*

```

[△ 14 ▽](#)

[R7RS](#)

[define-record-type](#) [索引](#)

实现

```
goldfish/scheme/base.scm
; 0-clause BSD by Bill Schottstaedt from S7 source repo: r7rs.scm
(define-macro (define-record-type type make ? . fields)
  (let ((obj (gensym))
        (typ (gensym)) ; this means each call on this macro makes a new type
        (args (map (lambda (field)
                     (values (list 'quote (car field))
                             (let ((par (memq (car field) (cdr make))))
                               (and (pair? par) (car par)))))
                  fields)))
    '(begin
      (define (,? ,obj)
        (and (let? ,obj)
             (eq? (let-ref ,obj ',typ) ',type)))

      (define ,make
        (inlet ',typ ',type ,@args))

      ,@(map
          (lambda (field)
            (when (pair? field)
              (if (null? (cdr field))
                  (values)
                  (if (null? (cddr field))
                      '(define (,(cadr field) ,obj)
                        (let-ref ,obj ,(car field)))
                      '(begin
                        (define (,(cadr field) ,obj)
                          (let-ref ,obj ,(car field)))
                        (define (,(caddr field) ,obj val)
                          (let-set! ,obj ,(car field) val)))))))
          fields)
      ',type)))

```

测试

通过`define-record-type`, 定义了一种名为`pare`的记录类型, 其中`kons`是这种记录类型的构造器, `pare?`是谓词, `kar`和`kdr`是选择器, `set-kar!`是修改器。

```
tests/goldfish/liii/base-test.scm
```

△ 15 ▽

```
(define-record-type :pare
  (kons x y)
  pare?
  (x kar set-kar!)
  (y kdr))

(check (pare? (kons 1 2)) => #t)
(check (pare? (cons 1 2)) => #f)
(check (kar (kons 1 2)) => 1)
(check (kdr (kons 1 2)) => 2)

(check
  (let ((k (kons 1 2)))
    (set-kar! k 3)
    (kar k))
  => 3)
```

上面那个例子比较难懂，提供一个更易懂的例子：

```
tests/goldfish/liii/base-test.scm ▲ 16 ▽
(define-record-type :person
  (make-person name age)
  person?
  (name get-name set-name!)
  (age get-age))

(check (person? (make-person "Da" 3)) => #t)
(check (get-age (make-person "Da" 3)) => 3)
(check (get-name (make-person "Da" 3)) => "Da")
(check
  (let ((da (make-person "Da" 3)))
    (set-name! da "Darcy")
    (get-name da))
  => "Darcy")
```

SRFI

```
goldfish/srfi/srfi-9.scm
(define-library (srfi srfi-9)
  (import (scheme base))
  (export define-record-type)
  (begin
    ) ; end of begin
  ) ; end of define-library
```

3.6 相等性判断

3.7 数

```

3.12 字符串

见章 9

3.13 向量

见章 10

3.14 字节向量

字节向量是固定长度的单字节序列，每一个单字节的取值范围是[0, 255]。字节向量的每一个元素都是类型一致的单字节，其空间利用率会比向量高一些。

类型一致的向量在S7 Scheme中有`int-vector`和`byte-vector`等特殊形式，这是S7 Scheme里面扩展的功能。R7RS定义的`bytevector`可以使用`byte-vector`作为实现。

[R7RS](#)[索引](#)

`bytevector (byte ...)` => `bytevector`

`byte.` 一个或多个介于 0 到 255 之间的整数（代表字节的值）。

`bytevector`过程返回一个新分配的字节向量，其元素包含传递给过程的所有参数。每个参数都必须是一个介于 0 到 255 之间的整数，表示字节向量中的一个字节。如果没有提供任何参数，将创建一个空的字节向量。

goldfish/liii/base.scm △ 3 ▽
(define* (u8-substring str (start 0) (end #t))
  (utf8->string (string->utf8 str start end)))
```

```
tests/goldfish/liii/base-test.scm △ 55 ▽
(check (u8-substring "汉字书写" 0 1) => "汉")
(check (u8-substring "汉字书写" 0 4) => "汉字书")
(check (u8-substring "汉字书写" 0) => "汉字书写")
```

3.15 控制流

procedure? [索引](#)

apply [索引](#)

`apply`是R7RS定义的函数。

```
tests/goldfish/liii/base-test.scm △ 56 ▽
(check (apply + (list 3 4)) => 7)
(check (apply + (list 2 3 4)) => 9)
```

在这个例子中，`(apply + (list 3 4))`实际被展开为`(+ 3 4)`。`+`这个函数接受两个参数，但是无法接受一个列表，利用`apply`就可以把列表展开并作为`+`的两个参数。

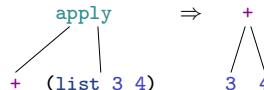

图 3.1. `apply`的原理可视化

call-with-current-continuation

call/cc

values [索引](#)

`values`是一个过程（procedure），它用于返回多个值。在 Scheme 中，通常的过程只能返回一个值，但是`values`允许你从一个过程返回多个值，这些值可以被另一个过程接收并处理。

当我们只传一个值给`values`时（比如`(values 4)`），它就简单地返回这个值，这时`values`的行为就像一个恒等函数。这是最简单的使用场景。

如果调用`values`时不带任何参数（即`(values)`），它会返回一个空值。这种情况在实践中比较少见，但在某些特殊场合可能会用到。

```
tests/goldfish/liii/base-test.scm △ 57 ▽
(check (values 4) => 4)
(check (values) => #<unspecified>)
```

在金鱼Scheme中，`values`的用法有一些特别之处，它允许将多个值直接插入到调用者的参数列表中。这种特性使得金鱼Scheme在处理多个返回值时非常灵活和强大。以下是`values`在金鱼Scheme中的一些特殊用法（这些特殊用法源自于S7 Scheme）：

直接插入到调用者参数列表. 使用`values`生成的多个值会被直接插入到调用者的参数列表中。这意味着，如果你有一个接受多个参数的函数，你可以直接从`values`获得的多个值中解构这些参数。

tests/goldfish/liii/base-test.scm

```
(check (+ (values 1 2 3) 4) => 10)
```

△ 58 ▽

这里，`values`生成的三个值(1 2 3)被直接插入到`+`函数的参数列表中，相当于(`+ 1 2 3 4`)。

与lambda配合使用. 当使用`lambda`表达式时，`values`也可以直接将多个值插入到参数列表中：

tests/goldfish/liii/base-test.scm

```
(check (string-ref ((lambda () (values "abcd" 2)))) => #\c)
```

△ 59 ▽

这里，`values`生成的字符串"abcd"和整数2被直接插入到`string-ref`函数的参数列表中，相当于(`(string-ref "abcd" 2)`)。

values与call/cc的隐式使用. `call/cc` (call with current continuation) 是一个特殊的函数，它接受一个返回多个值的过程，并将其值作为参数传递给一个消费者。在金鱼Scheme中，`call/cc`有一个隐式的`values`，这意味着你可以直接返回多个值：

tests/goldfish/liii/base-test.scm

```
(check (+ (call/cc (lambda (ret) (ret 1 2 3))) 4) => 10)
```

△ 60 ▽

这里，`ret`宏生成的多个值(1 2 3)被`+`函数接收并求和。

这些特性使得金鱼Scheme在处理多个返回值时非常灵活，允许程序员以一种直观和高效的方式编写代码。

R7RS
call-with-values (producer consumer)

tests/goldfish/liii/base-test.scm

```
(check (call-with-values (lambda () (values 4 5))
                         (lambda (x y) x))
      => 4)
```

△ 61 ▽

由于`*`这个函数在没有参数时返回1，而在只有一个参数的时候，返回该值的相反数。故而下面这个测试用例的返回值是`-1`。

tests/goldfish/liii/base-test.scm

```
(check (*) => 1)
(check (call-with-values * -) => -1)
```

△ 62 ▽

receive

官网：<https://srfi.schemers.org/srfi-8/srfi-8.html>

官网的参考实现是：

```
(define-syntax receive
  (syntax-rules ()
    ((receive formals expression body ...)
```

```
(call-with-values (lambda () expression)
  ((lambda formals body ...))))
```

但是S7 Scheme里面没有define-syntax和syntax-rule, 在墨干中的实现是这样的:

```
> (define-macro (receive vars vals . body)
  '((lambda ,vars ,@body) ,vals)) ; GPL
receive
> (receive (a b) (values 1 2) (+ a b))
> ((lambda (a b) (+ a b)) 1 2)
>
```

S7里面有call-with-values, 使用define-macro就可以实现SRFI-8。

goldfish/srfi/srfi-8.scm

3.17.3 输出

3.18 系统接口

3.19 三鲤扩展函数

==**|(x y) => bool**

equal?的语法糖。

[goldfish/liii/base.scm](#)

△ 4 ▽

`(define == equal?)`[tests/goldfish/liii/base-test.scm](#)

△ 67 ▽

`(check (== (list 1 2) (list 1 2)) => #t)``(check (!= (list 1 2) (list 1 2)) => #f)`**!=****|(x y) => bool**

语法糖。

[goldfish/liii/base.scm](#)

△ 5 ▽

`(define (!= left right)
 (not (equal? left right)))`

```
tests/goldfish/liii/base-test.scm
(check (== (list 1 2) (list 1 2)) => #t)
(check (!= (list 1 2) (list 1 2)) => #f)
```

△ 68 ▽

display* [索引] `(x y z ...) => <#unspecified>`

display*可以输入多个参数，是display的加强版。

```
goldfish/liii/base.scm
(define (display* . params)
  (for-each display params))
```

△ 6 ▽

```
tests/goldfish/liii/base-test.scm
```

△ 69 ▽

```
(check
  (with-output-to-string
    (lambda ()
      (display* "hello\uworld" "\n")))
  => "hello\uworld\n")
```

in? [索引] `((x sequence) => bool)`

判断一个元素是否在对象中：

1. 一个元素是否在列表中
2. 一个元素是否在向量中
3. 一个字符是否在字符串中

其中的相等性判断使用的是`==`，也就是R7RS定义的`equal?`。

```
tests/goldfish/liii/base-test.scm
(check (in? 1 (list )) => #f)
(check (in? 1 (list 3 2 1)) => #t)
(check (in? #\x "texmacs") => #t)
(check (in? 1 (vector )) => #f)
(check (in? 1 (vector 3 2 1)) => #t)
(check-catch 'type-error (in? 1 "123"))
```

△ 70 ▽

```
goldfish/liii/base.scm
```

△ 7 ▽

```
(define (in? elem l)
  (cond ((list? l) (not (not (member elem l))))
        ((vector? l)
         (let loop ((i (- (vector-length l) 1)))
           (if (< i 0)
               #f
               (if (== elem (vector-ref l i))
                   #t
                   (loop (- i 1)))))))
        ((and (char? elem) (string? l))
         (in? elem (string->list l)))
        (else (error 'type-error "type\uismatch"))))
```

let1 [索引]

let的语法嵌套层次太多了，故而引入let1，作为let的单参数版本，简化语法。

```
goldfish/liii/base.scm
(define-macro (let1 name1 value1 . body)
  '(let ((,name1 ,value1))
    ,@body))
```

△ 8 ▽

```

5.2 接口

将`check:proc`导出的原因是`check`是使用宏实现的，而宏里面用到了`check:proc`，不导出无法生效。

[goldfish/liii/check.scm](#)

△ 2 ▽

```

(define-library (liii check)
  (export test check check-set-mode! check:proc
          check-catch check-report check-failed?
          check-true check-false)
  (import (srfi srfi-78)
          (rename (srfi srfi-78)
                 (check-report srfi-78-check-report)))
  (begin
```

[goldfish/srfi/srfi-78.scm](#)

△ 2 ▽

```

(define-library (srfi srfi-78)
  (export check check-set-mode! check-report check-reset!
          check-passed? check-failed?
          check:proc)
  (begin
```

5.3 实现

使用`display`作为测试结果的展示函数，比`write`好，因为`display`可以正常显示文本中的汉字。

[goldfish/srfi/srfi-78.scm](#)

△ 3 ▽

```
(define check:write display)
```

goldfish/srfi/srfi-78.scm

△ 4 ▽

```
(define check-mode #f)

(define (check-set-mode! mode)
  (set! check-mode
    (case mode
      ((off)        0)
      ((summary)    1)
      ((report-failed) 10)
      ((report)     100)
      (else (error "unrecognized\_mode" mode))))
```

将检查模式初始化为`'report'`:

goldfish/srfi/srfi-78.scm

△ 5 ▽

```
(check-set-mode! 'report)
```

以`check`函数为例，不同的检查模式下，得到的结果不同。可以使用单元测试来查看这四种测试用例具体使用方法：

tests/goldfish/srfi/srfi-78-test.scm

△ 2 ▽

```
(import (srfi srfi-78))
```

report. 默认检查模式，无论正确还是错误，都会展示详细的信息。

tests/goldfish/srfi/srfi-78-test.scm

△ 3 ▽

```
; Copyright (C) 2024 The Goldfish Scheme Authors
;
; Licensed under the Apache License, Version 2.0 (the "License");
; you may not use this file except in compliance with the License.
; You may obtain a copy of the License at
;
; http://www.apache.org/licenses/LICENSE-2.0
;
; Unless required by applicable law or agreed to in writing, software
; distributed under the License is distributed on an "AS-IS" BASIS, WITHOUT
; WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied. See the
; License for the specific language governing permissions and limitations
; under the License.
;

(display "-----\n")
(display "check\_mode:\_report\n")

(check-set-mode! 'report)

(check (+ 1 2) => 3)

(check (+ 1 2) => 4)

(check-reset!)
```

off. 设置为off的时候，禁用后续的测试用例。

```
tests/goldfish/srfi/srfi-78-test.scm
(display "\n-----\n")
(display "check\u2022mode:\u2022off\n")

(check-set-mode! 'off)

(check (+ 1 2) => 3)

(check (+ 1 2) => 4)

(check-reset!)
```

△ 4 ▽

report-failed. 设置为report-failed的时候，在check正确时只返回正确的测试数量，在check错误时，显示错误。

```
tests/goldfish/srfi/srfi-78-test.scm
(display "\n-----\n")
(display "check\u2022mode:\u2022report-failed\n")

(check-set-mode! 'report-failed)

(check (+ 1 2) => 3)

(check (+ 1 2) => 4)

(check-reset!)
```

△ 5 ▽

summary. 设置为summary的时候，不汇报错误，需要显示调用`check-report`才能显示的测试汇总结果，显式调用`check:failed`显式查看错误的例子。

```
tests/goldfish/srfi/srfi-78-test.scm
(display "\n-----\n")
(display "check\u2022mode:\u2022summary\n")

(check-set-mode! 'summary)

(check (+ 1 2) => 3)

(check (+ 1 2) => 4)

(check-report)
```

△ 6 ▽

这个时候如果需要查看错误，那么可以重新设置检查模式，重新检查报告：

```
tests/goldfish/srfi/srfi-78-test.scm
(check-set-mode! 'report)

(check-report)
```

△ 7

goldfish/srfi/srfi-78.scm

△ 6 ▽

```
(define check:correct 0)
(define check:failed '())

(define (check-reset!)
  (set! check:correct 0)
  (set! check:failed '()))

(define (check:add-correct!)
  (set! check:correct (+ check:correct 1)))

(define (check:add-failed! expression actual-result expected-result)
  (set! check:failed
    (cons (list expression actual-result expected-result)
      check:failed)))
```

goldfish/srfi/srfi-78.scm

△ 7 ▽

```
(define (check:report-expression expression)
  (newline)
  (check:write expression)
  (display "↙=>↙"))

(define (check:report-actual-result actual-result)
  (check:write actual-result)
  (display "↙;↙"))

(define (check:report-correct cases)
  (display "correct")
  (if (not (= cases 1))
    (begin (display "↙(")
      (display cases)
      (display "↙cases↙checked)")))
  (newline))

(define (check:report-failed expected-result)
  (display "***↙failed↙***")
  (newline)
  (display ";↙expected↙result:↙")
  (check:write expected-result)
  (newline))

(define (check-passed? expected-total-count)
  (and (= (length check:failed) 0)
    (= check:correct expected-total-count)))

(define (check-failed?)
  (>= (length check:failed) 1))
```

check 索引

check的具体过程，依据不同的检查模式，做不同的处理：

goldfish/srfi/srfi-78.scm

```
(define (check:proc expression thunk equal expected-result)
  (case check:mode
    ((0) #f)
    ((1)
     (let ((actual-result (thunk)))
       (if (equal actual-result expected-result)
           (check:add-correct!)
           (check:add-failed! expression actual-result expected-result))))
    ((10)
     (let ((actual-result (thunk)))
       (if (equal actual-result expected-result)
           (check:add-correct!)
           (begin
             (check:report-expression expression)
             (check:report-actual-result actual-result)
             (check:report-failed expected-result)
             (check:add-failed! expression actual-result expected-result))))))
    ((100)
     (check:report-expression expression)
     (let ((actual-result (thunk)))
       (check:report-actual-result actual-result)
       (if (equal actual-result expected-result)
           (begin (check:report-correct 1)
                  (check:add-correct!))
           (begin (check:report-failed expected-result)
                  (check:add-failed! expression
                                      actual-result
                                      expected-result))))))
     (else (error "unrecognized\_check:mode" check:mode))))
```

△ 8 ▽

check的接口实现，使用S7 Scheme的**define-macro**实现：

goldfish/srfi/srfi-78.scm

```
(define-macro (check expr => expected)
  '(check:proc ',expr (lambda () ,expr) equal? ,expected))
```

△ 9 ▽

check-true

goldfish/liii/check.scm

```
(define-macro (check-true body)
  '(check ,body => #t))
```

△ 3 ▽

check-false

goldfish/liii/check.scm

```
(define-macro (check-false body)
  '(check ,body => #f))
```

△ 4 ▽

check-catch

goldfish/liii/check.scm

```
(define-macro (check-catch error-id body)

7.2 接口

Liii List函数库是金鱼标准库中的List函数库，其中的大部分函数来自函数库(`srfi srfi-1`)，小部分是三鲤自己设计的函数。来自SRFI 1的，我们只是在Liii List中导出相关函数名，相关实现和单元测试都在SRFI 1中维护。

goldfish/liii/list.scm

```
(define-library (liii list)
  (export
    ; S7 built-in
    cons car cdr map for-each
    ; SRFI 1: Constructors
    circular-list iota list-copy
    ; SRFI 1: Predicates
    null-list? circular-list? proper-list? dotted-list?
    ; SRFI 1: Selectors
    first second third fourth fifth sixth seventh eighth ninth tenth
    take drop take-right drop-right split-at
    last-pair last
    ; SRFI 1: fold, unfold & map
    count fold fold-right reduce reduce-right
    filter partition remove append-map
    ; SRFI 1: Searching
    find any every list-index
    take-while drop-while
    ; SRFI 1: Deleting
    delete
    ; SRFI 1: Association List
    assoc assq assv alist-cons
    ; Liii List extensions
    list-view flatmap
    list-null? list-not-null? not-null-list?
    length=? length>? length>=? flatten
  )
  (import (srfi srfi-1)
          (liii error))
  (begin
```

△ 2 ▽

```
goldfish/srfi/srfi-1.scm
(define-library (srfi srfi-1)
  (import (liii error)
          (liii base))
  (export
    ; SRFI 1: Constructors
    circular-list iota list-copy
    ; SRFI 1: Predicates
    circular-list? null-list? proper-list? dotted-list?
    ; SRFI 1: Selectors
    first second third fourth fifth
    sixth seventh eighth ninth tenth
    take drop take-right drop-right count fold fold-right split-at
    reduce reduce-right append-map filter partition remove find
    delete delete-duplicates
    ; SRFI 1: Association List
    assoc assq assv alist-cons
    take-while drop-while list-index any every
    last-pair last)
  (begin
```

7.3 测试

在金鱼Scheme中的SRFI 1实现需要遵循最小依赖原则，目前`delete-duplicates`是一个复杂度比较高的实现，在SRFI 1中保留，但并不在(`liii list`)导出，故而在本测试文件的开头需要从(`srfi srfi-1`)单独导入。

```
tests/goldfish/liii/list-test.scm
(import (liii list)
       (liii check)
       (only (srfi srfi-1) delete-duplicates))

(check-set-mode! 'report-failed)
```

7.4 SRFI-1

SRFI-1中有一部分函数已经在R7RS的(`scheme base`)库里面了。本节包含了R7RS定义的(`scheme base`)里面和列表相关的函数，这些函数的实现和测试均在`base.scm`和`base-test.scm`中维护。用户可以通过(`import (liii base)`)导入这些函数，或者使用(`import (liii list)`)导入这些函数。

7.4.1 构造器

R7RS 索引

`cons` S7 Scheme内置的R7RS中定义的函数。

R7RS 索引

`list` S7 Scheme内置的R7RS中定义的函数。

`make-list` (`make-list k [fill]`) => `list`

S7 Scheme内置的R7RS中定义的函数。

```
tests/goldfish/liii/base-test.scm
(check (make-list 3 #\a) => (list #\a #\a #\a))
(check (make-list 3) => (list #f #f #f))
(check (make-list 0) => (list ))
```

iota 索引

goldfish/srfi/srfi-1.scm △ 3 ▽

```
; 0 clause BSD, from S7 repo stuff.scm
(define* (iota n (start 0) (incr 1))
  (when (not (integer? n))
    (type-error "iota:~n~must~be~a~integer"))
  (when (< n 0)
    (value-error "iota:~n~must~be~positive~but~received~d" n))
  (let ((lst (make-list n)))
    (do ((p lst (cdr p))
         (i start (+ i incr)))
        ((null? p) lst)
        (set! (car p) i))))
```

测试用例

tests/goldfish/lili/list-test.scm △ 3 ▽

```
(check (iota 3) => (list 0 1 2))
(check (iota 3 7) => (list 7 8 9))
(check (iota 2 7 2) => (list 7 9))

(check-catch 'value-error (iota -1))
(check-catch 'type-error (iota 'a))
```

list-copy 索引

goldfish/scheme/base.scm △ 39 ▽

```
; 0 clause BSD, from S7 repo r7rs.scm
(define list-copy copy)
```

测试用例

tests/goldfish/lili/list-test.scm △ 4 ▽

```
;; list-copy tests

;; Check that copying an empty list works as expected
(check (list-copy '()) => '())

;; Check that copying a list of numbers works correctly
(check (list-copy '(1 2 3 4 5)) => '(1 2 3 4 5))

;; Check that copying a list of symbols works correctly
(check (list-copy '(a b c d)) => '(a b c d))

;; Check that copying nested lists works correctly
(check (list-copy '((1 2) (3 4) (5 6))) => '((1 2) (3 4) (5 6)))

;; Check that copying the list does not result in the same object
(check-false (eq? (list-copy '(1 2 3)) '(1 2 3)))

;; Check if list-copy is a deep copy or not
(let ((obj1 '(1 2 3 4))
      (obj2 (list-copy '(1 2 3 4))))
  (check obj1 => obj2)
  (set-car! obj1 3)
  (check-false (eq? obj1 obj2)))
```

7.4.2 谓词

[R7RS](#) [索引](#)
pair? (obj) => bool

pair?是S7 Scheme内置的函数：当且仅当obj是序对时，返回真。

tests/goldfish/liii/base-test.scm

```
(check-true (pair? '(a . b)))
(check-true (pair? '(a b c)))

(check-false (pair? '()))
(check-false (pair? '#(a b)))
```

△ 77 ▽

[R7RS](#) [索引](#)
list? (obj) => bool

基本列表测试：检查空列表和包含元素的列表是否被识别为列表。

tests/goldfish/liii/base-test.scm

```
(check-true (list? '()))
(check-true (list? '(a)))
(check-true (list? '(a b c)))
(check-true (list? '(1 . 2)))
(check-true (list? '(1 2 . 3)))
```

△ 78 ▽

嵌套列表测试：检查包含其他列表作为元素的列表是否被正确识别。

tests/goldfish/liii/base-test.scm

```
(check-true (list? '((a) (b) (c))))
(check-true (list? '(a (b) c)))
```

△ 79 ▽

循环列表测试：检查函数是否能够正确处理循环列表结构。

tests/goldfish/liii/base-test.scm

```
(check-true (list? (let ((x '(1 2 3))) (set-cdr! (cddr x) x))))
```

△ 80 ▽

非列表测试：检查基本数据类型以及向量是否被正确地识别为非列表。

tests/goldfish/liii/base-test.scm

```
(check-false (list? #t))
(check-false (list? #f))
(check-false (list? 123))
(check-false (list? "Hello"))
(check-false (list? '#(1 2 3)))
(check-false (list? '#()))
(check-false (list? '12345))
```

△ 81 ▽

[R7RS](#) [索引](#)
null? (obj) => bool

null?是S7 Scheme内置的函数：当且仅当obj是空列表的时候，返回值为真。

tests/goldfish/liii/base-test.scm

```
(check (null? '()) => #t)
(check (null? '(1)) => #f)
(check (null? '(1 2)) => #f)
```

△ 82 ▽

proper-list?

正规列表（proper list）是指满足以下条件的列表：

1. 空列表：也写作 ()，它是唯一的一个既是正规列表也是空列表的数据结构。空列表在 Scheme 中被认为是正规列表。

2. 非空列表：如果一个列表的每个元素都是通过 `cons` 过程构造的，并且该列表的 `cdr` 部分是正规列表，那么这个列表就是正规列表。

上述递归定义中，该列表通过 `cons` 过程构造保证了列表不会是循环列表。在判断一个列表是否是正规列表时，我们需要考虑该列表是循环列表的这种情况。

`goldfish/srfi/srfi-1.scm` △ 4 ▽

```
(define (proper-list? x)
  (let loop ((x x) (lag x))
    (if (pair? x)
        (let ((x (cdr x)))
          (if (pair? x)
              (let ((x (cdr x)))
                (lag (cdr lag)))
              (and (not (eq? x lag)) (loop x lag)))
              (null? x)))
        (null? x))))
```

`tests/goldfish/liii/list-test.scm` △ 5 ▽

```
(check-true (proper-list? (list 1 2)))
(check-true (proper-list? '()))
(check-true (proper-list? '(1 2 3)))

(check-false (proper-list? '(a . b)))
(check-false (proper-list? '(a b . c)))
(check-false (proper-list? (circular-list 1 2 3))))
```

dotted-list?

点状列表 (dotted list) 是一种列表：

空的点状列表。不是空列表、不是序对的任意 Scheme 对象都是空的点状列表

非空点状列表。其中除了最后一个元素之外，其他元素的 `cdr` 指向另一个元素，最后一个元素的 `cdr` 指向一个空的点状列表。

`goldfish/srfi/srfi-1.scm` △ 5 ▽

```
(define (dotted-list? x)
  (let loop ((x x) (lag x))
    (if (pair? x)
        (let ((x (cdr x)))
          (if (pair? x)
              (let ((x (cdr x)))
                (lag (cdr lag)))
              (and (not (eq? x lag)) (loop x lag)))
              (not (null? x))))
        (not (null? x)))))
```

`tests/goldfish/liii/list-test.scm` △ 6 ▽

```
(check-true (dotted-list? 1))
(check-true (dotted-list? '(1 . 2)))
(check-true (dotted-list? '(1 2 . 3)))

(check-false (dotted-list? (circular-list 1 2 3)))
(check-false (dotted-list? '()))
(check-false (dotted-list? '(a))))
```

[索引](#)
null-list?

null-list?是一个函数，返回#t当且仅当参数是空列表。当参数为空列表，返回#t；否则报错。

goldfish/srfi/srfi-1.scm

△ 6 ▽

```
(define (null-list? l)
  (cond ((pair? l) #f)
        ((null? l) #t)
        (else
         (error 'wrong-type-arg "null-list?: argument out of domain" l))))
```

tests/goldfish/liii/list-test.scm

△ 7 ▽

```
(check (null-list? '()) => #t)
```

当参数为序对，返回#f。

tests/goldfish/liii/list-test.scm

△ 8 ▽

```
(check (null-list? '(1 . 2)) => #f)
```

当参数为非空列表，返回#f。

tests/goldfish/liii/list-test.scm

△ 9 ▽

```
(check (null-list? '(1 2)) => #f)
```

当参数既不是序对也不是列表，报错。

辨析：null?在参数为非序对时，不报错，只是返回#f。

tests/goldfish/liii/list-test.scm

△ 10 ▽

```
(check (null? 1) => #f)
```

如果已经确定需要判别的对象是列表，使用null-list?更加合适。null?无法分辨非空的序对和非空的列表，命名上偏模糊，不推荐使用。

7.4.3 选择器

[R7RS](#) [索引](#)

car

一个序对由<car>部分与<cdr>部分组成，形如：(<car> . <cdr>)。car是S7 Scheme内置的R7RS定义的函数，用于返回序对的<car>部分。car的参数必须是序对，否则报错；特别地，空列表不是序对，报错。

tests/goldfish/liii/base-test.scm

△ 83 ▽

```
(check (car '(a b c . d)) => 'a)
      (check (car '(a b c)) => 'a))
```

```
(check-catch 'wrong-type-arg (car '()))
```

[R7RS](#) [索引](#)

cdr

cdr是S7 Scheme内置的R7RS定义的函数，用于返回序对的<cdr>部分。cdr的参数必须是序对，否则报错；特别地，空列表不是序对，报错。

tests/goldfish/liii/base-test.scm

△ 84 ▽

```
(check (cdr '(a b c . d)) => '(b c . d))
      (check (cdr '(a b c)) => '(b c)))
```

```
(check-catch 'wrong-type-arg (cdr '()))
```

caar 索引 (caar pair) => obj

caar是S7 Scheme内置的R7RS定义的函数，用于返回序对<car>部分的<car>部分。参数必须是序对，且该序对的<car>部分的内容也要是序对，否则报错。特别地，空列表不是序对，报错。

tests/goldfish/liii/base-test.scm

△ 85 ▽

(check (caar '((a . b) . c)) => 'a)

(check-catch 'wrong-type-arg (caar '(a b . c)))

(check-catch 'wrong-type-arg (caar '()))

R7RS

索引

list-ref

list-ref是S7 Scheme内置的R7RS定义的函数，接收一个列表和一个称为索引值的非负整数k为参数，通过索引值k返回列表的第k个元素（从0开始计数）。当参数为空列表时，报错。当k为负数，报错。当k大于等于列表中元素数时，报错。

注意(cons '(1 2) '(3 4))其实是一个列表，但这个列表的元素不都是整数。这个例子容易理解成结果是一个序对且不是列表。

> (cons '(1 2) '(3 4))

>

tests/goldfish/liii/base-test.scm

△ 24 ▽

`(check (drop-right '(1 2 3 4) 2) => '(1 2))`
`(check (drop-right '(1 2 3 4) 4) => '())`
`(check (drop-right '(1 2 3 . 4) 3) => '())`
`(check-catch 'out-of-range (drop-right '(1 2 3 4) 5))`
`(check-catch 'out-of-range (drop-right '(1 2 3 4) -1))`
`(check-catch 'out-of-range (drop-right '(1 2 3 . 4) 4))`

`split-at (lst i) => (values taked droped)`

[索引]

`lst.` 列表，需要被分割的列表。

i. 整数，指定分割的位置。

(values taked droped). 两个值，第一个是包含原列表前 i 个元素的列表，第二个是原列表剩余元素的列表。

将一个列表分割成两部分，返回两个值。第一个值是包含原列表前 i 个元素的列表，第二个值是原列表剩余元素的列表。

实现细节：该函数通过迭代方式工作。它遍历列表 `lst`，每次迭代将当前元素添加到结果列表中，直到达到指定的分割位置 `i`。如果 `i` 为 0，函数返回空列表和原始列表。如果 `i` 大于列表长度或小于 0，函数报错。函数使用 `values` 返回两个值，这样可以同时返回两个列表。

goldfish/srfi/srfi-1.scm ▲ 21 ▽

```
(define (split-at lst i)
  (when (< i 0)
    (value-error "require-a-index-greater-than-0, but got ~A---split-at" i))
  (let ((result (cons #f '())))
    (do ((j i (- j 1))
         (rest lst (cdr rest))
         (node result (cdr node)))
        ((zero? j)
         (values (cdr result) rest))
      (when (not (pair? rest))
        (value-error "list-length-cannot-be-greater-than-i, where list is ~A, but i is ~A---sp"
          (set-cdr! node (cons (car rest) '()))))))
```

tests/goldfish/liii/list-test.scm ▲ 25 ▽

```
(check (list (split-at '(1 2 3 4 5) 3)) => '((1 2 3) (4 5)))
(check (list (split-at '(1 2 3 4 5) 0)) => '(() (1 2 3 4 5)))

(check-catch 'value-error (split-at '(1 2 3 4 5) 10))
(check-catch 'value-error (split-at '(1 2 3 4 5) -1))

(check (list (split-at '(1 2 3 4 . 5) 0)) => '(() (1 2 3 4 . 5)))
(check (list (split-at '(1 2 3 4 . 5) 3)) => '((1 2 3) (4 . 5)))
(check (list (split-at '(1 2 3 4 . 5) 4)) => '((1 2 3 4) 5))

(check-catch 'value-error (split-at '() 10))
(check-catch 'value-error (split-at '() -1))
```

last-pair [索引] ▲ 22 ▽

`last-pair` 是一个函数，以序对形式返回列表的最后一个元素，参数必须是序对，空列表报错。

goldfish/srfi/srfi-1.scm

```
(define (last-pair l)
  (if (pair? (cdr l))
    (last-pair (cdr l))
    l))
```

tests/goldfish/liii/list-test.scm ▲ 26 ▽

```
(check (last-pair '(a b c)) => '(c))
(check (last-pair '(c)) => '(c))

(check (last-pair '(a b . c)) => '(b . c))
(check (last-pair '(b . c)) => '(b . c))

(check-catch 'wrong-type-arg (last-pair '()))
```

last

last是一个函数，以符号形式返回列表的最后一个元素，参数必须是序对，空列表报错。

goldfish/srfi/srfi-1.scm △ 23 ▽
(define (last l)
(car (last-pair l)))

tests/goldfish/liii/list-test.scm △ 27 ▽
(check (last '(a b c)) => 'c)
(check (last '(c)) => 'c)

(check (last '(a b . c)) => 'b)
(check (last '(b . c)) => 'b)

(check-catch 'wrong-type-arg (last '()))

7.4.4 常用函数

R7RS **length** (lst) -> integer 索引

length是一个S7内置函数，它接收一个列表为参数，返回该列表中元素的数量。如果参数不是列表，返回0。

tests/goldfish/liii/base-test.scm △ 88 ▽
(check (length ()) => 0)
(check (length '(a b c)) => 3)
(check (length '(a (b) (c d e))) => 3)

(check (length 2) => #f)
(check (length '(a . b)) => -1)

R7RS **append** 索引

append是一个S7内置的R7RS定义的函数，它接收多个列表为参数，按顺序拼接在一起，返回一个新的列表。**append**没有参数时，返回空列表。

tests/goldfish/liii/base-test.scm △ 89 ▽
(check (append '(a) '(b c d)) => '(a b c d))
(check (append '(a b) 'c) => '(a b . c))

(check (append () 'c) => 'c)
(check (append) => '())

R7RS **reverse** 索引

tests/goldfish/liii/base-test.scm △ 90 ▽
(check (reverse '()) => '())
(check (reverse '(a)) => '(a))
(check (reverse '(a b)) => '(b a))

count 索引

`count`是一个高阶函数，它接收两个参数：一个谓词和一个列表；返回满足谓词条件的元素在列表中出现的次数。

goldfish/srfi/srfi-1.scm

△ 24 ▽

```
(define (count pred list1 . lists)
  (let lp ((lis list1) (i 0))
    (if (null-list? lis) i
        (lp (cdr lis) (if (pred (car lis)) (+ i 1) i)))))
```

tests/goldfish/liii/list-test.scm

△ 28 ▽

```
(check (count even? '(3 1 4 1 5 9 2 5 6)) => 3)
```

7.4.5 折叠和映射

R7RS 索引
map

`map`是S7的内置高阶函数，它接收一个函数和一个列表为参数，把该函数应用于该列表的每个元素上，并返回一个新列表。

tests/goldfish/liii/base-test.scm

△ 91 ▽

```
(check (map square (list 1 2 3 4 5)) => '(1 4 9 16 25))
```

R7RS

索引
for-each (for-each proc list1 [list2 ...])

`for-each`是S7内置的高阶函数。`for-each`的参数与`map`的参数类似，但`for-each`调用`proc`是为了它的副作用，而不是为了它的返回值。与`map`不同，`for-each`保证会按照从第一个元素到最后一个元素的顺序调用`proc`，并且`for-each`返回的值是未指定的。如果给出了多个列表，并且不是所有列表的长度都相同，`for-each`会在最短的列表用尽时终止。当`proc`不接受与`lists`数量相同的参数，报错。

tests/goldfish/liii/base-test.scm

△ 92 ▽

```
(check
  (let ((v (make-vector 5)))
    (for-each (lambda (i) (vector-set! v i (* i i)))
              (iota 5)))
  v)
=> #(0 1 4 9 16))
```

(check

```
  (let ((v (make-vector 5 #f)))
    (for-each (lambda (i) (vector-set! v i (* i i)))
              (iota 4)))
  v)
=> #(0 1 4 9 #f))
```

(check

```
  (let ((v (make-vector 5 #f)))
    (for-each (lambda (i) (vector-set! v i (* i i)))
              (iota 0)))
  v)
=> #(#f #f #f #f #f))
```

fold

`fold`是一个高阶函数，它接受三个参数：一个函数、一个初始值和一个列表，将函数累积地应用到一个列表的所有元素上，从左到右，从而将列表折叠成一个单一的值。

goldfish/srfi/srfi-1.scm ▲ 25 ▽

```
(define (fold f initial 1)
  (when (not (procedure? f))
    (error 'type-error "The first parameter must be a procedure"))
  (if (null? l)
    initial
    (fold f
      (f (car l) initial)
      (cdr l))))
```

这是SRFI-1官方提供的实现，我们暂时不用。

```
(define (fold kons knil lis1 . lists)
  (if (pair? lists)
    (let lp ((lists (cons lis1 lists)) (ans knil))
      (receive (cars+ans cdrs) (%cars+cdrs+ lists ans)
        (if (null? cars+ans) ans
          (lp cdrs (apply kons cars+ans)))))

    (let lp ((lis lis1) (ans knil))
      (if (null-list? lis) ans
        (lp (cdr lis) (kons (car lis) ans)))))
```

常见的用法：

从初始值开始，依次累加列表中的元素，返回一个数；当列表为空列表时，返回初始值。

tests/goldfish/liii/list-test.scm ▲ 29 ▽

```
(check (fold + 0 '(1 2 3 4)) => 10)
(check (fold + 0 '()) => 0)

(check-catch 'type-error (fold 0 + '(1 2 3 4)))
```

反转列表中的元素，返回一个新列表。

tests/goldfish/liii/list-test.scm ▲ 30 ▽

```
(check (fold cons () '(1 2 3 4)) => '(4 3 2 1))
```

统计列表中满足谓词的元素数量，返回这个数量。

tests/goldfish/liii/list-test.scm ▲ 31 ▽

```
(check
  (fold (lambda (x count) (if (symbol? x) (+ count 1) count))
    0
    '(a b 1 2 3 4))
  => 2)
```

fold-right

`fold-right`与`fold`类似，不同的是，`fold-right`是从右到左折叠。

```
goldfish/srfi/srfi-1.scm
(define (fold-right f initial l)
  (if (null? l)
      initial
      (f (car l)
          (fold-right f
                      initial
                      (cdr l)))))
```

这是SRFI-1官方提供的实现，我们暂时不用：

```
(define (fold-right kons knil lis1 . lists)
  (if (pair? lists)
      (let recur ((lists (cons lis1 lists)))
        (let ((cdrs (%cdrs lists)))
          (if (null? cdrs) knil
              (apply kons (%cars+ lists (recur cdrs)))))))

      (let recur ((lis lis1))
        (if (null-list? lis) knil
            (let ((head (car lis)))
              (kons head (recur (cdr lis))))))))
```

在用作累加、统计时，`fold-right`与`fold`的结果是相同的。

```
tests/goldfish/liii/list-test.scm
(check (fold-right + 0 '(1 2 3 4)) => 10)

(check (fold-right + 0 '()) => 0)

(check
  (fold-right (lambda (x count) (if (symbol? x) (+ count 1) count))
              0
              '(a b 1 2 3 4))
  =>
  2)
```

但`fold-right`与`fold`的折叠方向是相反的，这就使得列表原本的顺序得以保持，不会反转。

```
tests/goldfish/liii/list-test.scm
(check (fold-right cons () '(1 2 3 4)) => '(1 2 3 4))
```

`reduce`

`reduce`与`fold`类似，但有微妙且关键的不同。只有在列表为空列表时，才会使用这个初始值。在列表不是空列表时，则把列表的`<car>`部分取出作为`fold`的初始值，又把列表的`<cdr>`部分取出作为`fold`的列表。

```
goldfish/srfi/srfi-1.scm
(define (reduce f initial l)
  (if (null-list? l) initial
      (fold f (car l) (cdr l))))
```

在用作累加时，`reduce`与`fold`的结果是相同的。

```
tests/goldfish/liii/list-test.scm
(check (reduce + 0 '(1 2 3 4)) => 10)
(check (reduce + 0 '()) => 0)
```

不适用于反转列表中的元素，但当列表非空，返回的不再是列表，而是序对。因为`reduce`会把非空列表的第一个元素取出来作为`fold`的初始值。

[tests/goldfish/liii/list-test.scm](#) △ 35 ▽
`(check (reduce cons () '(1 2 3 4)) => '(4 3 2 . 1))`

不适用于统计列表中满足谓词的元素数量，因为`reduce`会把非空列表的第一个元素取出来作为`fold`的初始值，引发错误。

[tests/goldfish/liii/list-test.scm](#) △ 36 ▽
`(check-catch 'wrong-type-arg
 (reduce (lambda (x count) (if (symbol? x) (+ count 1) count))
 0
 '(a b 1 2 3 4)))`

[reduce-right](#) 索引
`reduce-right`与`reduce`类似，不同的是，`reduce-right`是从右到左规约。

[goldfish/srfi/srfi-1.scm](#) △ 28 ▽
`(define (reduce-right f initial l)
 (if (null-list? l) initial
 (let recur ((head (car l)) (l (cdr l)))
 (if (pair? l)
 (f head (recur (car l) (cdr l)))
 head))))`

在用作累加时，`reduce-right`与`fold`的结果是相同的。

[tests/goldfish/liii/list-test.scm](#) △ 37 ▽
`(check (reduce-right + 0 '(1 2 3 4)) => 10)`
`(check (reduce-right + 0 '()) => 0)`

也不适用于重列列表中的元素，以及统计列表中满足谓词的元素数量。

[tests/goldfish/liii/list-test.scm](#) △ 38 ▽
`(check (reduce-right cons () '(1 2 3 4))
=> '(1 2 3 . 4))`
`(check
(reduce-right (lambda (x count) (if (symbol? x) (+ count 1) count))
0
'(a b 1 2 3 4))
=> 6)`

[append-map](#) 索引
`append-map`
[goldfish/srfi/srfi-1.scm](#) △ 29 ▽
`(define append-map
(typed-lambda ((proc procedure?) (lst list?))
(let loop ((rest lst)
(result '()))
(if (null? rest)
result
(loop (cdr rest)
(append result (proc (car rest)))))))`

7.4.6 过滤和分组

[filter](#)

`filter`是一个高阶函数，接收一个谓词和一个列表为参数，从这个列表中筛选出满足谓词的元素，组成一个新列表，返回这个新列表。

goldfish/srfi/srfi-1.scm

△ 30 ▽

```
(define (filter pred l)
  (let recur ((l l))
    (if (null-list? l) l
        (let ((head (car l))
              (tail (cdr l)))
          (if (pred head)
              (let ((new-tail (recur tail)))
                (if (eq? tail new-tail) l
                    (cons head new-tail)))
              (recur tail)))))))
```

tests/goldfish/liii/list-test.scm

△ 39 ▽

```
(check (filter even? '(-2 -1 0 1 2)) => '(-2 0 2)))
```

[partition](#)

`partition`是一个高阶函数，接收一个谓词和一个列表为参数，从这个列表中分别筛选出满足和不满足谓词的元素，各组成一个新列表，返回以这两个新列表组成的序对。

goldfish/srfi/srfi-1.scm

△ 31 ▽

```
(define (partition pred l)
  (let loop ((lst l) (satisfies '()) (dissatisfies '()))
    (cond ((null? lst)
            (cons satisfies dissatisfies))
          ((pred (car lst))
           (loop (cdr lst) (cons (car lst) satisfies) dissatisfies))
          (else
           (loop (cdr lst) satisfies (cons (car lst) dissatisfies)))))))
```

tests/goldfish/liii/list-test.scm

△ 40 ▽

```
(check
  (partition symbol? '(one 2 3 four five 6))
  => (cons '(five four one) '(6 3 2))))
```

[remove](#)

`remove`是一个高阶函数，接收一个谓词和一个列表为参数，从这个列表中去掉满足谓词的元素，组成一个新列表，返回这个新列表。

goldfish/srfi/srfi-1.scm

△ 32 ▽

```
(define (remove pred l)
  (filter (lambda (x) (not (pred x))) l))
```

tests/goldfish/liii/list-test.scm

△ 41 ▽

```
(check (remove even? '(-2 -1 0 1 2)) => '(-1 1)))
```

7.4.7 搜索

[索引](#)

memq

`memq`是一个S7内置函数，和`member`类似，但判断元素等价的谓词是`eq?`。也就是说，检查的是两个元素在是否是同一个实例，即它们是否具有相同的内存地址。

对比使用`equal?`的`member`或使用`eqv?`的`memv`，这种检查最为“严格”，适用于判断的元素类型最少，速度最快，适用于判断布尔值（#t、#f）、符号、整数（浮点数和复数不行）、函数（的值）这些类型的元素是否在列表中。

[tests/goldfish/liii/base-test.scm](#)

△ 93 ▽

```
(check (memq #f '(1 #f 2 3)) => '(#f 2 3))
(check (memq 'a '(1 a 2 3)) => '(a 2 3))
(check (memq 2 '(1 2 3)) => '(2 3))

(check (memq 2.0 '(1 2.0 3)) => #f)
(check (memq 2+0i '(1 2+0i 3)) => #f)

(define num1 3)
(define num2 3)
(check (memq num1 '(3 num2)) => '(3 num2))
(check (memq 3 '(num1 num2)) => #f)
(check (memq 'num1 '(num1 num2)) => '(num1 num2))

(check (memq (+ 1 1) '(1 2 3)) => '(2 3))
```

[索引](#)

memv

`memv`是一个S7内置函数，和`member`类似，但判断元素元素的谓词是`eqv?`。也就是说，检查的是两个元素是否相同或在数值上等价。

比使用`equal?`的`member`“严格”，但比使用`eq?`的`memq`“宽松”，适用于判断的元素类型次全（`memv`能实现的功能`member`都能实现），速度中等，适用于判断数值类元素（整数、浮点数、复数）是否在列表中。但是注意，即使数值相同也不视为同一元素。

[tests/goldfish/liii/base-test.scm](#)

△ 94 ▽

```
(check (memv 2 '(1 2 3)) => '(2 3))
(check (memv 2.0 '(1 2.0 3)) => '(2.0 3))
(check (memv 2+0i '(1 2+0i 3)) => '(2+0i 3))

(check (memv 2 '(1 2.0 3)) => #f)
(check (memv 2 '(1 2+0i 3)) => #f)
```

[索引](#)

member

`member`是一个S7内置函数，接收一个元素和一个列表为参数，返回包含该元素的第一个子列表。当元素不在列表中，返回#f。当列表为空列表，返回#f。

[tests/goldfish/liii/base-test.scm](#)

△ 95 ▽

```
(check (member 2 '(1 2 3)) => '(2 3))
(check (member 0 '(1 2 3)) => #f)
(check (member 0 '()) => #f)
```

注意，判断两个元素等价的谓词是`equal?`。也就是说，检查的是两个元素在结构和内容上是否等价。

对比使用`eq?`的`memq`或使用`eqv?`的`memv`，这种检查最为“宽松”，适用于判断的元素类型最全，但速度最慢（因为它会递归地比较复合数据结构的每个部分），建议用于判断字符串、序对、列表这些类型的元素是否在列表中，如果无需判断这些类型，建议选用`memv`或`memq`。

[tests/goldfish/liii/base-test.scm](#) △ 96 ▽

```
(check (member "1" '(0 "1" 2 3)) => '("1" 2 3))
(check (member '(1 . 2) '(0 (1 . 2) 3)) => '((1 . 2) 3))
(check (member '(1 2) '(0 (1 2) 3)) => '((1 2) 3))
```

 **find**

find是一个高阶函数，接收一个谓词和一个列表为参数，返回该列表中第一个满足谓词的元素。当列表为空列表，或列表中没有满足谓词的元素，返回#f。

[goldfish/srfi/srfi-1.scm](#) △ 33 ▽

```
(define (find pred l)
  (cond ((null? l) #f)
        ((pred (car l)) (car l))
        (else (find pred (cdr l))))))
```

[tests/goldfish/liii/list-test.scm](#) △ 42 ▽

```
(check (find even? '(3 1 4 1 5 9)) => 4)
```

```
(check (find even? '()) => #f)
```

```
(check (find even? '(1 3 5 7 9)) => #f)
```

 **take-while**

take-while是一个高阶函数，接收一个谓词和一个列表为参数，按列表顺序筛选出满足谓词的元素，直到不满足谓词的那个一个就停止筛选，返回筛选出的元素组成的列表。

[goldfish/srfi/srfi-1.scm](#) △ 34 ▽

```
(define (take-while pred lst)
  (if (null? lst)
      '()
      (if (pred (car lst))
          (cons (car lst) (take-while pred (cdr lst)))
          '()))))
```

当参数的列表为空列表，无论谓词是什么都返回空列表。

[tests/goldfish/liii/list-test.scm](#) △ 43 ▽

```
(check (take-while even? '()) => '())
```

当列表中所有元素都满足谓词，返回原列表。

[tests/goldfish/liii/list-test.scm](#) △ 44 ▽

```
(check (take-while (lambda (x) #t) '(1 2 3))
      => '(1 2 3))
```

当列表中没有元素满足谓词，返回空列表。

[tests/goldfish/liii/list-test.scm](#) △ 45 ▽

```
(check
  (take-while (lambda (x) #f) '(1 2 3))
  => '())
```

当列表的第一个元素就不满足谓词，返回空列表。

tests/goldfish/liii/list-test.scm

△ 46 ▽

```
(check
  (take-while (lambda (x) (not (= x 1))) '(1 2 3))
  => '())
```

筛选元素的过程按照列表的顺序进行，当一个元素已经不满足谓词，那么这个元素之后的元素不会被筛选出。

tests/goldfish/liii/list-test.scm

△ 47 ▽

```
(check
  (take-while (lambda (x) (< x 3)) '(1 2 3 0))
  => '(1 2))
```

[索引](#)

drop-while是一个高阶函数，接收一个谓词和一个列表为参数，按列表顺序丢掉满足谓词的元素，直到不满足谓词的那个一个就停止丢掉，返回剩下的元素组成的列表。

goldfish/srfi/srfi-1.scm

△ 35 ▽

```
(define (drop-while pred l)
  (if (null? l)
      '()
      (if (pred (car l))
          (drop-while pred (cdr l))
          l)))
```

当列表为空列表，返回空列表。

tests/goldfish/liii/list-test.scm

△ 48 ▽

```
(check (drop-while even? '()) => '())
```

当列表中所有元素都满足谓词，返回空列表。

7.4.10 循环列表

[索引](#)

circular-list

使用该构造器构造的列表是循环列表，每一个循环的单元包含构造器中的所有参数。

[goldfish/srfi/srfi-1.scm](#) △ 43 ▽

```
(define (circular-list val1 . vals)
  (let ((ans (cons val1 vals)))
    (set-cdr! (last-pair ans) ans)
    ans))
```

[tests/goldfish/liii/list-test.scm](#) △ 62 ▽

```
(let1 cl (circular-list 1 2 3)
  (check (cl 3) => 1)
  (check (cl 4) => 2)
  (check (cl 5) => 3)
  (check (cl 6) => 1))
```

[索引](#)

circular-list?

判断一个列表是不是循环列表，这里采用的是判断链表这个数据结构的是否循环的经典算法，使用两个指针，第一个指针每轮迭代移动两次，第二个指针每轮迭代移动一次，如果两个指针在某一次迭代中指向的是同一个位置，那么该列表就是循环列表。

[goldfish/srfi/srfi-1.scm](#) △ 44 ▽

```
(define (circular-list? x)
  (let loop ((x x) (lag x))
    (and (pair? x)
         (let ((x (cdr x)))
           (and (pair? x)
                (let ((x (cdr x)))
                  (and (pair? x)
                       (let ((x (cdr x)))
                         (and (pair? x)
                              (let ((x (cdr x)))
                                (and (pair? x)
                                     (or (eq? x lag) (loop x lag))))))))))))
```

测试

[tests/goldfish/liii/list-test.scm](#) △ 63 ▽

```
(check-true (circular-list? (circular-list 1 2)))
(check-true (circular-list? (circular-list 1)))

(let* ((l (list 1 2 3))
       (end (last-pair l)))
  (set-cdr! end (cdr l))
  (check-true (circular-list? l)))

(check-false (circular-list? (list 1 2))))
```

7.5 三鲤扩展函数

[索引](#)

length=? [\(x 1\) => boolean](#)

- x. 期望的列表长度，如果长度为负数，该函数会抛出value-error

1. 列表

快速判断一个列表`l`的长度是否为`x`。由于(`= x (length l)`)这种判断方式的复杂度是 $O(n)$ ，故而需要`length=?`这种快速的判断方式。

```
tests/goldfish/liii/list-test.scm △ 64 ▽
(define (check-true (length=? 3 (list 1 2 3)))
(define (check-false (length=? 2 (list 1 2 3)))
(define (check-false (length=? 4 (list 1 2 3)))

(define (check-true (length=? 0 (list ))))
(define (check-catch 'value-error (length=? -1 (list ))))
```

```
goldfish/liii/list.scm △ 3 ▽
(define (length=? x scheme-list)
  (when (< x 0)
    (value-error "length=?: expected non-negative integer, but received ~d" x))
  (cond ((and (= x 0) (null? scheme-list)) #t)
        ((or (= x 0) (null? scheme-list)) #f)
        (else (length=? (- x 1) (cdr scheme-list))))))
```

`length>?` (lst len) => bool 索引

使用贪心策略，先访问列表的前`len`个元素，如果列表长度不大于`len`，那么返回布尔值假，否则返回布尔值真。`lst`并不一定是严格意义上的列表（最后一个元素是空列表），也可能是序对。

```
goldfish/liii/list.scm △ 4 ▽
(define (length>? lst len)
  (let loop ((lst lst)
            (cnt 0))
    (cond ((null? lst) (< len cnt))
          ((pair? lst) (loop (cdr lst) (+ cnt 1)))
          (else (< len cnt)))))
```

```
tests/goldfish/liii/list-test.scm △ 65 ▽
(define (check-true (length>? '(1 2 3 4 5) 3))
(define (check-false (length>? '(1 2) 3))
(define (check-false (length>? '() 0))

(define (check-true (length>? '(1) 0)))
(define (check-false (length>? '() 1))

(define (check-false (length>? '(1 2 . 3) 2)))
(define (check-true (length>? '(1 2 . 3) 1)))
```

`length>=?` (lst len) => bool 索引

使用贪心策略，先访问列表的前`len`个元素，如果列表长度小于`len`，那么返回布尔值假，否则返回布尔值真。`lst`并不一定是严格意义上的列表（最后一个元素是空列表），也可能是序对。

```
goldfish/liii/list.scm △ 5 ▽
(define (length>=? lst len)
  (let loop ((lst lst)
            (cnt 0))
    (cond ((null? lst) (<= len cnt))
          ((pair? lst) (loop (cdr lst) (+ cnt 1)))
          (else (<= len cnt)))))
```

```
tests/goldfish/liii/list-test.scm
(check-true (length=? '(1 2 3 4 5) 3))
(check-false (length=? '(1 2) 3))
(check-true (length=? '() 0))

(check-true (length=? '(1) 0))
(check-false (length=? '() 1))

(check-false (length=? '(1 2 . 3) 3))
(check-true (length=? '(1 2 . 3) 2))
```

list-view

由于Scheme的List和数据的流向是相反的：

```
(map (lambda (x) (* x x))
     (map (lambda (x) (+ x 1))
          (list 1 2 3)))
```

所以我们实现了list-view，采用和Scala的List类似的语法来处理数据：

```
tests/goldfish/liii/list-test.scm
(check ((list-view (list 1 2 3))) => (list 1 2 3))

(check (((list-view (list 1 2 3))
         map (lambda (x) (+ x 1)))) => (list 2 3 4))

(check (((list-view (list 1 2 3))
         map (lambda (x) (+ x 1)))
        map (lambda (x) (* x x))))
      => (list 4 9 16))
```

(list-view 1 2 3)得到的是函数，需要在外面再加一层括号才能得到(list 1 2 3)。

```
(map (lambda (x) (* x x))
      (map (lambda (x) (+ x 1))
            (list 1 2 3)))           (((list-view 1 2 3)
                                         map (lambda (x) (+ x 1)))
                                         map (lambda (x) (* x x))))
```

图 7.1. 使用list处理数据和使用list-view处理数据的对比

实现list-view时需要考虑三种情况和一种例外情况。

无参数. 也就是直接在list-view得到的结果外面添加括号，此时得到的是list-view对应的list

有两个参数. 这里举例说明，((list-view 1 2 3) map (lambda (x) (+ x 1)))实际的计算过程是：

1. 计算并得到结果 (map (lambda (x) (+ x 1)) (list 1 2 3)) => (list 2 3 4)
2. 将计算结果包装到list-view里面，这里使用了apply这个内置函数

其实也是树的转换：

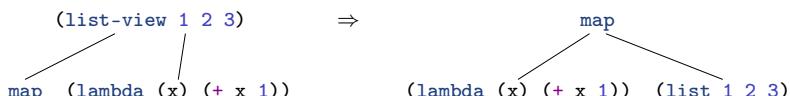

图 7.2. 原理的可视化

偶数个参数. 在上述两个递归退出条件写好的情况下, 在思考这种一般的情况。

需要计算((list-view 1 2 3) hf1 f1 hf2 f2 ... hfn fn), 其中hf指的是high-order function, 也就是高阶函数。也就是需要计算:

```
((((list-view 1 2 3) hf1 f1) hf2 f2) ... hfn fn)
```

goldfish/liii/list.scm

△ 6 ▽

```
(define (list-view scheme-list)
  (define (f-inner-reducer scheme-list filter filter-func rest-funcs)
    (cond ((null? rest-funcs) (list-view (filter filter-func scheme-list)))
          (else
            (f-inner-reducer (filter filter-func scheme-list)
                            (car rest-funcs)
                            (cadr rest-funcs)
                            (cddr rest-funcs)))))

  (define (f-inner . funcs)
    (cond ((null? funcs) scheme-list)
          ((length=? 2 funcs)
           (list-view ((car funcs) (cadr funcs) scheme-list)))
          ((even? (length funcs))
           (f-inner-reducer scheme-list
                           (car funcs)
                           (cadr funcs)
                           (cddr funcs)))
          (else (error 'wrong-number-of-args
                        "list-view only accepts even number of args"))))

  f-inner)
```

flatmap

索引

goldfish/liii/list.scm

△ 7 ▽

```
(define flatmap append-map)
```

(check (list-not-null? '(a . b)) => #f)
(check (list-null? '(a . b)) => #f)

(check-catch 'type-error (not-null-list? 1))
(check (list-not-null? 1) => #f)
(check (list-null? 1) => #f)
```

flatten 
(lst [depth]) => lst

(lst [depth]) => lst

压平 lst, 压为更扁的形状。直观来说, 去掉内层列表的括号。例如, (flatten '(a b (c (d)) (e) ((f)))) 'deepest) => (a b c d e f)。参数 depth 可选, 默认为 1, 指定最深压平层数, depth 为 n 时, 最深压平 n 层列表, depth 为 'deepest 时, 压平整个列表。

注意, 定义 flatten 应当使用 `define*` 而非 `define` 以支持可选参数。

```
goldfish/liii/list.scm
(define* (flatten lst (depth 1))
```

包装一般化的 flatten, 使用 `set-cdr!` 加速构建列表,

[goldfish/liii/list.scm](#)

```
(define (flatten-depth-iter rest depth res-node)
  (if (null? rest)
      res-node
      (let ((first (car rest))
            (tail (cdr rest)))
        (cond ((and (null? first) (not (= 0 depth)))
               (flatten-depth-iter tail depth res-node))
              ((or (= depth 0) (not (pair? first))))
               (set-cdr! res-node (cons first '())))
              (flatten-depth-iter tail depth (cdr res-node)))
          (else
            (flatten-depth-iter
              tail
              depth
              (flatten-depth-iter
                first
                (- depth 1)
                res-node)))))))
```

因为要 `set-cdr!` 参数 `res-node`，所以必须保证后者是 pair，不能是 null。为达成这个目的，可以先 `cons` 一个 pair，之后返回它的 `<cdr>`。

[goldfish/liii/list.scm](#)

```
(define (flatten-depth lst depth)
  (let ((res (cons #f '())))
    (flatten-depth-iter lst depth res)
    (cdr res)))
```

注意到 `flatten-depth-iter` 迭代中 (`cond` 第二个子句)，不断传递 `depth` 参数，只是重新绑定而不加改变。然而 goldfish 访问自由变量不比直接传递参数效率更高，只好辗转传递 `depth`。`(flatten-depth lst -1)` 固然可以用来实现 `(flatten lst -1)`，但总是额外传递一个无意义的参数 `depth`，效率较低，可以针对这一点进行优化。

[goldfish/liii/list.scm](#)

```
(define (flatten-deepest-iter rest res-node)
  (if (null? rest)
      res-node
      (let ((first (car rest))
            (tail (cdr rest)))
        (cond ((pair? first)
               (flatten-deepest-iter
                 tail
                 (flatten-deepest-iter
                   first
                   res-node)))
              ((null? first)
               (flatten-deepest-iter tail res-node))
              (else
                (set-cdr! res-node (cons first '()))
                (flatten-deepest-iter tail (cdr res-node))))))
  (define (flatten-deepest lst)
    (let ((res (cons #f '())))
      (flatten-deepest-iter lst res)
      (cdr res)))
```

最后，分派 flatten-depth 和 flatten-deepest。注意 flatten 参数 depth 不应该是除 n 和 deepest 以外的任何值，因而，当出现其它值时抛出错误。

goldfish/liii/list.scm ▲ 15 ▽

```
(cond ((eq? depth 'deepest)
       (flatten-deepest lst))
      ((integer? depth)
       (flatten-depth lst depth))
      (else
       (type-error
        (string-append
         "flatten: the second argument depth should be symbol"
         "'deepest' or an integer, which will be used as depth,"
         "but got ~A") depth)))
) ; end of (define* (flatten))
```

测试代码如下。

tests/goldfish/liii/list-test.scm ▲ 70 ▽

```
; deepest flatten
(check (flatten '((a) () (b ()) () (c)) 'deepest) => '(a b c))
(check (flatten '((a b) c (((d)) e)) 'deepest) => '(a b c d e))
(check (flatten '(a b () (c))) 'deepest) => '(a b c))
; depth flatten
(check (flatten '((a) () (b ()) () (c)) 0) => '((a) () (b ()) () (c)))
(check (flatten '((a) () (b ()) () (c)) 1) => '(a b () c))
(check (flatten '((a) () (b ()) () (c))) => '(a b () c))
(check (flatten '((a) () (b ()) () (c)) 2) => '(a b c))
(check (flatten '((a) () (b ()) () (c)) -1) => '(a b c))
(check (flatten '((a b) c (((d)) e)) 0) => '((a b) c (((d)) e)))
(check (flatten '((a b) c (((d)) e)) 1) => '(a b c ((d)) e))
(check (flatten '((a b) c (((d)) e))) => '(a b c ((d)) e))

第 8 章

(liii bitwise) [\[chapter:liii_bitwise\]](#)

8.1 概述

位运算的基本规则如下表所示：

表格 8.1. 二进制1位位运算表

	1 op 1	1 op 0	0 op 1	0 op 0
and	1	0	0	0
or	1	1	1	0
xor	0	1	1	0

在金鱼Scheme中，整数类型是64位的有符号整数，上述运算规则执行64次，就是金鱼Scheme中整数的位运算具体规则。

8.4 测试

[tests/goldfish/liii/bitwise-test.scm](#) △ 2 ▽

```
(import (liii check)
        (liii bitwise))

(check-set-mode! 'report-failed)
```

8.5 实现

8.5.1 基础运算

[lognot](#) 索引
[SRFI] [bitwise-not](#) 索引 ((x integer?)) => boolean?

使用S7内置的lognot实现，不推荐使用lognot。

[goldfish/srfi/srfi-151.scm](#) △ 3 ▽

```
(define bitwise-not lognot)
```

测试

[tests/goldfish/liii/bitwise-test.scm](#) △ 3 ▽

```
(check (bitwise-not 0) => -1)
(check (bitwise-not 1) => -2)
(check (bitwise-not #b1000) => -9)
(check (bitwise-not -1) => 0)
```

[logand](#) 索引
[SRFI] [bitwise-and](#) 索引 ((a integer?) (b integer?)) => boolean?

使用S7内置的logand实现，不推荐使用logand。此函数应用and运算在整数的二进制表示上。

[goldfish/srfi/srfi-151.scm](#) △ 4 ▽

```
(define bitwise-and logand)
```

测试

[tests/goldfish/liii/bitwise-test.scm](#) △ 4 ▽

```
(check (bitwise-and 5 3) => 1) ; 5 (101) AND 3 (011) = 1 (001)
(check (bitwise-and 8 4) => 0) ; 8 (1000) AND 4 (0100) = 0 (0000)
(check (bitwise-and #b101 #b011) => 1) ; 5 (101) AND 3 (011) = 1 (001)
(check (bitwise-and #b1000 #b0100) => 0) ; 8 (1000) AND 4 (0100) = 0 (0000)
(check (bitwise-and #b1100 #b1010) => 8)
```

logior 索引

bitwise-or 索引 ((a integer?) (b integer?)) => boolean?

使用S7内置的logior实现，不推荐使用logior。此函数应用or运算在整数的二进制表示上。

goldfish/srfi/srfi-151.scm

(define bitwise-ior logior)

△ 5 ▽

goldfish/liii/bitwise.scm

(define bitwise-or bitwise-ior)

△ 3 ▽

测试

tests/goldfish/liii/bitwise-test.scm

△ 5 ▽

```
(check (bitwise-ior 5 3) => 7) ; 5 (101) OR 3 (011) = 7 (111)
(check (bitwise-or 5 3) => 7)
(check (bitwise-ior 8 4) => 12) ; 8 (1000) OR 4 (0100) = 12 (1100)
(check (bitwise-ior #b101 #b011) => 7) ; 5 (101) AND 3 (011) = 1 (001)
(check (bitwise-ior #b1000 #b0100) => 12) ; 8 (1000) AND 4 (0100) = 0 (0000)
(check (bitwise-ior #b1100 #b0001) => 13)
```

logxor 索引

bitwise-xor 索引 ((a integer?) (b integer?)) => boolean?

使用S7内置的logxor实现，不推荐使用logxor，推荐使用bitwise-xor。

goldfish/srfi/srfi-151.scm

(define bitwise-xor logxor)

△ 6 ▽

测试

tests/goldfish/liii/bitwise-test.scm

△ 6 ▽

```
(check (bitwise-xor 1 1) => 0)
(check (bitwise-xor #b10 #b11) => #b01) ; 2 xor 3 = 1
(check (bitwise-xor #b101010 #b110100) => #b011110) ; 42 xor 20 = 34
(check (bitwise-xor #b0 #b0) => #b0) ; 0 xor 0 = 0
(check (bitwise-xor #b1 #b1) => #b0) ; 1 xor 1 = 0
(check (bitwise-xor #b101 #b111) => #b010) ; 5 xor 7 = 2
(check (bitwise-xor #b1000 #b1001) => #b0001) ; 8 xor 9 = 1
(check (bitwise-xor #b10010101 #b01111001) => #b11101100)
```

lognot 索引

bitwise-nor 索引 ((a integer?) (b integer?)) => boolean?

使用S7内置的lognot和bitwise-ior实现。

goldfish/srfi/srfi-151.scm

(define (bitwise-nor a b)
 (lognot (bitwise-ior a b)))

△ 7 ▽

测试

```
tests/goldfish/liii/bitwise-test.scm
(check (bitwise-nor 2 4) => -7)
(check (bitwise-nor 3 1) => -4)
(check (bitwise-nor #b111 #b011) => -8)
(check (bitwise-nor #b1101 #b1011) => -16)
(check (bitwise-nor #b1100 #b0000) => -13)
```

lognot 

 bitwise-nand  ((a integer?) (b integer?)) => boolean?

使用S7内置的lognot和bitwise-and实现。

```
goldfish/srfi/srfi-151.scm
```

△ 8 ▽

```
(define (bitwise-nand a b)
  (lognot (bitwise-and a b)))
```

测试

```
tests/goldfish/liii/bitwise-test.scm
```

△ 8 ▽

```
(check (bitwise-nand 1 1) => -2)
(check (bitwise-nand 3 1) => -2)
(check (bitwise-nand #b110 #b001) => -1)
(check (bitwise-nand #b1001 #b0111) => -2)
(check (bitwise-nand #b1011 #b0101) => -2)
```

 bit-count  ((i integer?)) => integer?

如果i是正数，统计i的二进制表示中的1的数量。如果i是负数，统计i的二进制表示中的0的数量。

```
goldfish/srfi/srfi-151.scm
```

△ 9 ▽

```
(define bit-count
  (typed-lambda ((i integer?))
    (define (bit-count-positive i)
      (let loop ((n i) (cnt 0))
        (if (= n 0)
            cnt
            (loop (logand n (- n 1)) (+ cnt 1)))))

    (cond ((zero? i) 0)
          ((positive? i) (bit-count-positive i))
          (else (bit-count-positive (lognot i))))))
```

测试

```
tests/goldfish/liii/bitwise-test.scm
```

△ 9 ▽

```
(check (bit-count 0) => 0)
(check (bit-count -1) => 0)
(check (bit-count 7) => 3)
(check (bit-count 13) => 3)
(check (bit-count -13) => 2)
(check (bit-count 30) => 4)
(check (bit-count -30) => 4)
(check (bit-count (arithmetic-shift #b10 61)) => 1)
```

[SRFI] **bitwise-orc1** **((a integer?) (b integer?)) => boolean?**

使用S7内置的bitwise-ior和bitwise-not实现。

goldfish/srfi/srfi-151.scm

△ 10 ▽

```
(define (bitwise-orc1 i j)
  (bitwise-ior (bitwise-not i) j))
```

测试

tests/goldfish/liii/bitwise-test.scm

△ 10 ▽

```
(check (bitwise-orc1 1 1) => -1)
(check (bitwise-orc1 3 1) => -3)
(check (bitwise-orc1 11 26) => -2)
(check (bitwise-orc1 #b110 #b001) => -7)
(check (bitwise-orc1 #b1001 #b0111) => -9)
(check (bitwise-orc1 #b1011 #b0101) => -11)
```

[SRFI] **bitwise-orc2** **((a integer?) (b integer?)) => boolean?**

使用S7内置的bitwise-ior和bitwise-not实现。

goldfish/srfi/srfi-151.scm

△ 11 ▽

```
(define (bitwise-orc2 i j)
  (bitwise-ior i (bitwise-not j)))
```

测试

tests/goldfish/liii/bitwise-test.scm

(check (bitwise-orc2 #b1011 #b0101) => -5)
```

[SRFI] **bitwise-andc1** **((a integer?) (b integer?)) => boolean?**

使用S7内置的bitwise-and和bitwise-not实现。

goldfish/srfi/srfi-151.scm

△ 12 ▽

```
(define (bitwise-andc1 i j)
  (bitwise-and (bitwise-not i) j))
```

测试

tests/goldfish/liii/bitwise-test.scm

△ 12 ▽

```
(check (bitwise-andc1 11 26) => 16)
(check (bitwise-andc1 5 3) => 2)
(check (bitwise-andc1 #b1100 #b1010) => 2)
(check (bitwise-andc1 0 15) => 15)
(check (bitwise-andc1 15 0) => 0)
(check (bitwise-andc1 7 1) => 0)
```

[SRFI] **bitwise-andc2** **((a integer?) (b integer?)) => boolean?**

使用S7内置的bitwise-and和bitwise-not实现。

[goldfish/srfi/srfi-151.scm](#)

```
(define (bitwise-andc2 i j)
  (bitwise-and i (bitwise-not j)))
```

测试

[tests/goldfish/liii/bitwise-test.scm](#)

```

(check (bitwise-andc2 5 3) => 4)
(check (bitwise-andc2 #b1100 #b1010) => 4)
(check (bitwise-andc2 0 15) => 0)
(check (bitwise-andc2 15 0) => 15)
(check (bitwise-andc2 7 1) => 6)
```

8.5.2 整数运算

ash [索引](#)

[SRFI](#) [索引](#) arithmetic-shift $((i \text{ integer?}) (\text{shift } \text{integer?})) \Rightarrow \text{integer?}$

log开头的S7内置函数不推荐使用，原因是log不符合位运算的语义，ash是arithmetic-shift的简写，能够有效避免arithmetic这个单词拼写错误的可能性，仍旧是推荐使用的。从代码可读性上考虑，还是使用arithmetic-shift更加合适。

[goldfish/srfi/srfi-151.scm](#)

```
(define arithmetic-shift ash)
```

测试

[tests/goldfish/liii/bitwise-test.scm](#)

```
(check (arithmetic-shift #b10 -1) => #b1) ; 2 >> 1 = 1
(check (arithmetic-shift #b10 1) => #b100) ; 2 << 1 = 4
(check (arithmetic-shift #b1000 -2) => #b10) ; 8 >> 2 = 2
(check (arithmetic-shift #b1000 2) => #b100000)
(check (arithmetic-shift #b1000000000000000 -3) => #b1000000000000000)
(check (arithmetic-shift #b1000000000000000 3) => #b1000000000000000)
```

9.4.2 谓词

[R7RS](#) [索引](#)

`string?`是一个S7内置的谓词函数，当且仅当参数对象类型是字符串（例如`"MathAgape"`）时返回`#t`，否则都返回`#f`。当参数为符号（例如`'MathAgape`）、字符（例如`#/MathAgape`）、数字（例如`123`）、列表（例如`(1 2 3)`）这些非字符串类型时，都返回`#f`。`string?`用于确定对象是否可以被当作字符串处理，在需要执行对字符串特定操作时特别有用，避免类型错误。

[tests/goldfish/liii/base-test.scm](#)

```
(check (string? "MathAgape") => #t)
(check (string? "") => #t)

(check (string? 'MathAgape) => #f)
(check (string? #/MathAgape) => #f)
(check (string? 123) => #f)
(check (string? '(1 2 3)) => #f)
```

9.4.3 列表-字符串转换

[R7RS](#) [索引](#)

`string->list`是一个S7内置的函数，用于将字符串转换为字符列表。

[tests/goldfish/liii/base-test.scm](#)

```
(check (string->list "MathAgape")
      => '(#\M #\a #\t #\h #\A #\g #\a #\p #\e))

(check (string->list "") => '())
```

[R7RS](#) [索引](#)

`list->string`是一个S7内置的函数，用于将字符列表转换为字符串。

[tests/goldfish/liii/base-test.scm](#)

```
(check
  (list->string '(#\M #\a #\t #\h #\A #\g #\a #\p #\e))
  => "MathAgape")

(check (list->string '()) => "")
```

`string-join (l [delim [grammar]]) => string`

实现

```
goldfish/srfi/srfi-13.scm
(define (string-join l . delim+grammar)
  (define (extract-params params-1)
    (cond ((null-list? params-1)
           (list ""))
          ((and (= (length params-1) 1)
                (string? (car params-1)))
           (list (car params-1) 'infix))
          ((and (= (length params-1) 2)
                (string? (first params-1)))
           (symbol? (second params-1)))
           params-1)
          ((> (length params-1) 2)
           (error 'wrong-number-of-args "optional-in-string-join"))
          (else (error 'type-error "optional-in-string-join"))))

  (define (string-join-sub l delim)
    (cond ((null-list? l) "")
          ((= (length l) 1) (car l))
          (else
            (string-append
              (car l)
              delim
              (string-join-sub (cdr l) delim)))))

  (let* ((params (extract-params delim+grammar))
         (delim (first params))
         (grammar (second params))
         (ret (string-join-sub l delim)))
    (case grammar
      ('infix ret)
      ('strict-infix
       (if (null-list? l)
           (error 'value-error "empty-list-not-allowed")
           ret))
      ('suffix
       (if (null-list? l) "" (string-append ret delim)))
      ('prefix
       (if (null-list? l) "" (string-append delim ret)))
      (else (error 'value-error "invalid-grammar")))))
```

测试

```
tests/goldfish/liii/string-test.scm
(check (string-join '("a" "b" "c")) => "abc")
(check (string-join '("a" "b" "c") ":")) => "a:b:c"
(check (string-join '("a" "b" "c") ":" 'infix)) => "a:b:c"
(check (string-join '("a" "b" "c") ":" 'suffix)) => "a:b:c:"
(check (string-join '("a" "b" "c") ":" 'prefix)) => ":a:b:c"

(check (string-join '() ":")) => ""
(check (string-join '() ":" 'infix)) => ""
(check (string-join '() ":" 'prefix)) => ""
(check (string-join '() ":" 'suffix)) => ""

(check-catch 'value-error (string-join '() ":" 'strict-infix))
(check-catch 'type-error (string-join '() ":" 2))
(check-catch 'value-error (string-join '() ":" 'no-such-grammar))
(check-catch 'wrong-number-of-args (string-join '() ":" 1 2 3))
```

9.4.4 谓词

[\[索引\]](#)
string-null? (*str*) => boolean

string-null?是一个谓词函数，当且仅当参数字符串为空（即长度为0）时返回#t，否则都返回#f，也就是说，当参数是非字符串或长度不为0的字符串时，返回#f。

```
goldfish/srfi/srfi-13.scm
(define (string-null? str)
  (and (string? str)
    ((lambda (x) (= x 0)) (string-length str))))
```

```
tests/goldfish/liii/string-test.scm
(check-true (string-null? ""))
(check-false (string-null? "MathAgape"))
(check-false (string-null? 'not-a-string))
```

string-every

[索引](#)

`string-every`是一个谓词函数，它接收一个字符串`str`和一个评估规则`criterion`为参数，以及最多2个非负整数为可选参数。`start-end`用于指定搜索的起始位置和结束位置，检查指定范围内字符串中的每个字符是否都满足评估规则`criterion`。

```
goldfish/srfi/srfi-13.scm
(define (string-every char/pred? str . start+end)
  (define (string-every-sub pred? str)
    (let
      (loop ((i 0) (len (string-length str)))
            (or (= i len)
                (and (pred? (string-ref str i))
                     (loop (+ i 1) len)))))

    (let ((str-sub (%string-from-range str start+end))
          (criterion (%make-criterion char/pred?)))
      (string-every-sub criterion str-sub))))
```

```
tests/goldfish/liii/string-test.scm
(check-true (string-every #\x "xxxxxx"))
(check-false (string-every #\x "xxx0xx"))

(check-true (string-every char-numeric? "012345"))
(check-false (string-every char-numeric? "012d45"))
```

注意，评估规则`criterion`必须是谓词或字符，否则报错。

```
tests/goldfish/liii/string-test.scm
(check-catch 'wrong-type-arg (string-every 1 "012345"))
(check-catch 'wrong-type-arg (string-every #\012345 "012345"))
(check-catch 'wrong-type-arg (string-every "012345" "012345"))
```

注意，谓词要使用字符属性测试函数（例如`char-numeric?`），不要用类型检查函数（例如`number?`），否则失去了检查的意义。

```
tests/goldfish/liii/string-test.scm
(check-true (string-every char-numeric? "012345"))
(check-false (string-every number? "012345"))
```

对于可选参数。`start-end`: 没有可选参数时，默认搜索整个字符串；只有1个可选参数时，该数指定的是起始位置，结束位置默认为字符串的最后一个字符。注意，有2个可选参数时，第二个数不能小于第一个数，否则报错；指定的起始位置和结束位置不能超过字符串`str`的起始范围，否则报错；可选参数超过2个时，报错。（注意，可选参数的规则适用于后面所有调用到`%string-from-range`的函

      (string-any
        char-alphabetic?
        "01c345"
        2
        1)))
    (lambda args #t))
  =>
  #t)
```

9.4.5 选择器

[R7RS](#) [索引](#)

`string-length`是一个S7内置的函数，它接收一个字符串作为参数，返回一个表示该字符串长度的整数，即字符串中包含的字符数。当参数不是字符串，报错。

```
tests/goldfish/liii/base-test.scm
(check (string-length "MathAgape") => 9)
(check (string-length "") => 0)

(check
  (catch 'wrong-type-arg
    (lambda () (string-length 'not-a-string)))
    (lambda args #t))
  =>
  #t)
```

[R7RS](#) [索引](#)

`string-ref`是一个S7内置的函数，接收一个字符串和一个称为索引值的非负整数k为参数，通过索引值k返回字符串的第k个元素（从0开始计数）。当参数为空字符串时，报错。当k为负数，报错。当

k大于等于字符串中字符数时，报错。

tests/goldfish/liii/base-test.scm △ 101 ▽

```
(check (string-ref "MathAgape" 0) => #\M)
(check (string-ref "MathAgape" 2) => #\t)

(check-catch 'out-of-range (string-ref "MathAgape" -1))
(check-catch 'out-of-range (string-ref "MathAgape" 9))
(check-catch 'out-of-range (string-ref "" 0))
```

[R7RS](#) [索引](#)

`string-copy`是一个S7内置的函数，用于创建一个现有字符串的副本。这个函数返回一个与原始字符串内容完全相同的新字符串，但它们在内存中是两个独立的实体。也就是说，原始字符串和副本字符串内容相同，但它们是不同的对象，这可以用`equal?`和`eq?`对比出来。

`string-copy`和`%string-from-range`的实现比较接近，区别在于：在没有指定字符串的范围的时候，我们需要使用`substring`来模拟整个字符串的拷贝。S7内置的函数只提供了整个字符串的拷贝，R7RS和SRFI-13是需要额外的字符串的范围的，所以需要重新实现。

goldfish/scheme/base.scm △ 40 ▽

```
(define (string-copy str . start_end)
  (cond ((null? start_end)
          (substring str 0))
        ((= (length start_end) 1)
         (substring str (car start_end))))
        ((= (length start_end) 2)
         (substring str (car start_end) (cadr start_end)))
        (else (error 'wrong-number-of-args))))
```

(check-catch 'type-error (vector-empty? 1))
```

`vector=`

使用一个元素比较器 (elt=?) 来比较传入的一组向量是否相等。当传入的向量不足两个的时候默认返回相等。元素比较器 elt=? 以及内置的比较器运算的结果都是 boolean，否则都会抛出类型错误。

因为比较一组向量是否全部相等，可以通过不断比较相邻两个来实现。所以这里的具体实现中，定义了一个名为 compare2vecs 的内部 procedure，它可以使用 elt=? 进行向量的两两比较。

goldfish/srfi/srfi-133.scm

△ 4 ▽

```
(define (vector= elt=? . rest)
  (define compare2vecs
    (typed-lambda ((cmp procedure?) (vec1 vector?) (vec2 vector?))
      (let* ((len1 (vector-length vec1))
             (len2 (vector-length vec2)))
        (if (not (= len1 len2)) #f
            (let loop ((ilhs 0) (irhs 0) (len len1))
              (if (= ilhs len) #t
                  (if (not (cmp (vec1 ilhs) (vec2 irhs))) #f
                      (loop (+ 1 ilhs) (+ 1 irhs) len)))))))
      (when (not (procedure? elt=?)) (error 'type-error "elt=? should be a procedure"))
      (if (or(null? rest) (= 1 (length rest))) #t
          (let loop ((vec1 (car rest)) (vec2 (car (cdr rest))) (vrest (cdr (cdr rest))))
            (let1 rst (compare2vecs elt=? vec1 vec2)
              (when (not (boolean? rst)) (error 'type-error "elt=> should return bool"))
              (if (compare2vecs elt=? vec1 vec2)
                  (if (null? vrest) #t
                      (loop vec2 (car vrest) (cdr vrest)))
                  #f)))))))
```

```
tests/goldfish/liii/vector-test.scm
; trivial cases

(check-false (vector= eq? (vector (vector 'a)) (vector (vector 'a))))
```

10.4.3 选择器

R7RS **vector-length** (v) => integer 索引

以整数返回向量中元素的数量。

```
tests/goldfish/liii/base-test.scm
(check (vector-length #(1 2 3)) => 3)
(check (vector-length #()) => 0)
```

R7RS **vector-ref** ((v vector?) (k integer?)) => object 索引

返回向量中索引为 k 的元素的内容。当 k 不是向量的有效索引，报错。

注意 10.1. 在金鱼Scheme中，我们推荐使用(v 0)而不是(vector-ref v 0)，因为前者更加简洁。在使用前者访问向量中的元素时，注意变量的命名需要能够标明变量的类型，比如在(x 0)中，我们无法有效分辨x是什么类型的变量，而(vector-ref x 0)能够有效地标明x是向量。故而，在使用前者这种简洁的语法时，建议使用v-前缀或者-v后缀来标明x的类型，比如(v-x 0)或者(x-v 0)。

```
tests/goldfish/liii/base-test.scm
(let1 v #(1 2 3)
  (check (vector-ref v 0) => 1)
  (check (v 0) => 1)

  (check (vector-ref v 2) => 3)
  (check (v 2) => 3))

  (check-catch 'out-of-range (vector-ref #(1 2 3) 3))
  (check-catch 'out-of-range (vector-ref #() 0))

  (check-catch 'wrong-type-arg (vector-ref #(1 2 3) 2.0))
  (check-catch 'wrong-type-arg (vector-ref #(1 2 3) "2"))
```

```

vector-cumulate

索引

实现

使用函数 fn 和初始值 knil 在向量 vector 上迭代，迭代结果将在一个等长的新向量中返回。

每次迭代中，fn 被传入上次迭代的结果 lhs 和向量中的元素 vec i，产生的结果 cumu-i 将存储在结果向量 v-rst 中。

一般而言，knil, cumu-i 的类型未必与 vector 中的元素相同，只需要保证 fn cumu-i (vec i) 能够得到 cumu-i 同类型的结果即可。

迭代过程可以形式地表示为：

vector-cumulate fn knil vec => #(fn knil (vec 0), fn cumu-0 (vec 1), fn cumu-1 (vec 2), ...)

goldfish/srfi/srfi-133.scm

△ 6 ▽

```
; Return a new vector v-rst with same length of input vector vec.
; Every element of the result is the result the i-th iteration of fn cumu_i vec_i.
;   Where fn should be a procedure with 2 args.
;   The type of knil and vector could be different.
; In the i-th iteration, cumu_i = fn cumu_(i-1) vec_i, with cumu_0 = fn knil vec_0.
```

```
(define vector-cumulate
  (typed-lambda ((fn procedure?) knil (vec vector?))
    (let* ((len (vector-length vec))
           (v-rst (make-vector len)))
      (let loop ((i 0) (lhs knil))
        (if (= i len)
            v-rst
            (let1 cumu-i (fn lhs (vec i)))
            (begin
              (vector-set! v-rst i cumu-i)
              (loop (+ 1 i) cumu-i)))))))

```

[R7RS](#) [vector-fill!](#)

goldfish/scheme/base.scm

```
(define vector-fill! fill!)
```

tests/goldfish/liii/vector-test.scm

```
(define my-vector (vector 0 1 2 3 4))
(fill! my-vector #f)
(check my-vector => #(#f #f #f #f #f))

(define my-vector (vector 0 1 2 3 4))
(fill! my-vector #f 1 2)
(check my-vector => #(0 #f 2 3 4))
```

[R7RS](#) [vector-copy!](#) [vector-copy!](#) to at from [start [end]]

to和from都是向量，vector-copy!就是从from向量复制元素依次粘贴到to向量，粘贴从to向量的第at个索引位置开始；start和end是可选参数，用于指定从from向量选取元素的范围。

```
a (vector "a0" "a1" "a2" "a3" "a4")
```

```
b (vector "b0" "b1" "b2" "b3" "b4"
```

(vector-copy! b 1 a 0 2) 就是：

第一步：从 a 中选取索引为 [0,2] 的元素，即 "a0" "a1"

第二步：定位到 b 的索引为 1 的位置，即 "b1" 所在的那个位置

第三步：以刚刚定位到的那个 "b1" 位置为起点，把刚刚选出的元素 "a0" "a1" 依次替换，直到

代码实现时要注意

at、to、from 的边界条件，按顺序写它们会导致报错的条件

要注意每一个参数在后面会遇到怎样的使用

第一步：只涉及单个参数的报错条件

```
(< at 0) 可省去  

```

第二步：两个依赖关系的参数的报错条件

```
(> start end)
```

第三步：三个依赖关系参数的报错条件

```
(> (+ at (- end start)) (vector-length to))
```

综合上方的报错条件，去掉一些多余的条件：

(< start 0) 可省去

因为有 (> (+ at (- end start)) (vector-length to))，所以 (> at (vector-length to)) 可省去

```
> (define a (vector "a0" "a1" "a2" "a3" "a4"))  
> (define b (vector "b0" "b1" "b2" "b3" "b4"))  
> (vector-copy! b 0 a 1)  
> b  
> a  

```

(check-catch 'out-of-range (vector-copy! b 1 a))

(define a (vector "a0" "a1" "a2" "a3" "a4"))
(define b (vector "b0" "b1" "b2" "b3" "b4"))
(vector-copy! b 0 a 1)
(check b => #("a1" "a2" "a3" "a4" "b4"))

(define a (vector "a0" "a1" "a2" "a3" "a4"))
(define b (vector "b0" "b1" "b2" "b3" "b4"))
(vector-copy! b 0 a 0 5)
(check b => #("a0" "a1" "a2" "a3" "a4"))
```

10.4.7 转换

R7RS `vector->list (vector->list v [start [end]])` 索引

返回一个新分配的列表，包含向量中从 `start` 到 `end` 之间的元素中的对象。当 `start`、`end` 不是向量的有效索引，报错。

```
tests/goldfish/liii/base-test.scm
(check (vector->list #()) => '())
(check (vector->list #() 0) => '())

(check-catch 'out-of-range (vector->list #() 1))

(check (vector->list #(0 1 2 3)) => '(0 1 2 3))
(check (vector->list #(0 1 2 3) 1) => '(1 2 3))
(check (vector->list #(0 1 2 3) 1 1) => '())
(check (vector->list #(0 1 2 3) 1 2) => '(1))
```

R7RS `list->vector (list->vector l)` 索引

返回一个新创建的向量，其元素初始化为列表 `list` 中的元素。注意 `vector` 不像 `list` 那样可用接收索引参数。

`tests/goldfish/liii/base-test.scm` △ 111

```
(check (list->vector '(0 1 2 3)) => #(0 1 2 3))
(check (list->vector '()) => #())
```

R7RS `reverse-list->vector` (`reverse-list->vector 1`) 索引

返回一个新创建的向量，其元素初始化为反转后的列表 `list` 中的元素。

传入的列表应当是一个 `proper-list`。

实现

`goldfish/srfi/srfi-133.scm` △ 13 ▽

```
; Input a proper-list, return a vector with inversed order elements.
(define reverse-list->vector
  (typed-lambda ((lst proper-list?))
    (let* ((len (length lst)) (v-rst (make-vector len)))
      (let loop ((l lst) (i (- len 1)))
        (if (null? l) v-rst
            (begin
              (vector-set! v-rst i (car l))
              (loop (cdr l) (- i 1)))))))
```

测试

常见情况：

`tests/goldfish/liii/vector-test.scm` △ 19 ▽

```
(check (reverse-list->vector '()) => '#())
(check (reverse-list->vector '(1 2 3)) => '#(3 2 1))
```

点状列表不是正规列表，故而会直接抛出 `type-error`：

`tests/goldfish/liii/vector-test.scm` △ 20 ▽

```
(check-catch 'type-error (reverse-list->vector '(1 2 . 3)))
```

循环列表不是正规列表，故而会直接抛出 `type-error`：

`tests/goldfish/liii/vector-test.scm` △ 21 ▽

```
(check-catch 'type-error (reverse-list->vector (circular-list 1 2 3)))
```

R7RS `vector->string` (`v [start [end]]`) 索引 => `string`

将向量 `v` 转化为字符串，如果指定了起始索引和终止索引，则只将指定范围内的子向量转化为字符串。

`goldfish/scheme/base.scm` △ 48 ▽

```
; 0-clause BSD
; Bill Schottstaedt
; from S7 source repo: r7rs.scm
(define* (vector->string v (start 0) end)
  (let ((stop (or end (length v))))
    (copy v (make-string (- stop start)) start stop)))
```

△ 22 ▽

```
tests/goldfish/liii/vector-test.scm
(check (vector->string (vector #\0 #\1 #\2 #\3)) => "0123")
(check (vector->string (vector #\a #\b #\c)) => "abc")

(check (vector->string (vector #\0 #\1 #\2 #\3) 0 4) => "0123")
(check (vector->string (vector #\0 #\1 #\2 #\3) 1) => "123")
(check (vector->string (vector #\0 #\1 #\2 #\3) 1 4) => "123")
(check (vector->string (vector #\0 #\1 #\2 #\3) 1 3) => "12")
(check (vector->string (vector #\0 #\1 #\2 #\3) 1 2) => "1")

(check-catch 'out-of-range (vector->string (vector #\0 #\1 #\2 #\3) 2 10))

(check (vector->string (vector 0 1 #\2 3 4) 2 3) => "2")

(check-catch 'wrong-type-arg (vector->string (vector 0 1 #\2 3 4) 1 3))
```

R7RS **string->vector** (s [start [end]]) => vector 索引

将字符串s转化为向量，如果指定了起始索引和终止索引，则只将指定范围内的子字符串转化为向量。

goldfish/scheme/base.scm

△ 49 ▽

```
; 0-clause BSD
; Bill Schottstaedt
; from S7 source repo: r7rs.scm
(define* (string->vector s (start 0) end)
  (let ((stop (or end (length s))))
    (copy s (make-vector (- stop start)) start stop)))
```

tests/goldfish/liii/vector-test.scm

△ 23 ▽

```
(check (string->vector "0123") => (vector #\0 #\1 #\2 #\3))
(check (string->vector "abc") => (vector #\a #\b #\c))

(check (string->vector "0123" 0 4) => (vector #\0 #\1 #\2 #\3))
(check (string->vector "0123" 1) => (vector #\1 #\2 #\3))
(check (string->vector "0123" 1 4) => (vector #\1 #\2 #\3))
(check (string->vector "0123" 1 3) => (vector #\1 #\2))
(check (string->vector "0123" 1 2) => (vector #\1))

(check-catch 'out-of-range (string->vector "0123" 2 10))
```

14.3.1 访问哈希表中的元素

除了SRFI 125定义的`hash-table-ref`和`hash-table-ref/default`之外，我们可以用S7 Scheme内置的访问方式：

```
tests/goldfish/liii/hash-table-test.scm
(let1 ht (make-hash-table)
  (check (ht 'a) => #f)
  (hash-table-set! ht 'a 1)
  (check (ht 'a) => 1))
```

14.4 实现

14.4.1 子函数

```
goldfish/srfi/srfi-125.scm
(define (assert-hash-table-type ht f)
  (when (not (hash-table? ht))
    (error 'type-error f "this parameter must be typed as hash-table")))
(define s7-hash-table-set! hash-table-set!)
(define s7-make-hash-table make-hash-table)
(define s7-hash-table-entries hash-table-entries)
```

14.4.2 构造器

make-hash-table 

goldfish/srfi/srfi-125.scm

```
(define (make-hash-table . args)
  (cond ((null? args) (s7-make-hash-table))
        ((comparator? (car args))
         (let* ((equiv (comparator-equality-predicate (car args)))
                (hash-func (comparator-hash-function (car args))))
            (s7-make-hash-table 8 (cons equiv hash-func) (cons #t #t))))
        (else (type-error "make-hash-table"))))
```

△ 4 ▽

tests/goldfish/liii/hash-table-test.scm

```
(let1 ht (make-hash-table (make-default-comparator))
  (hash-table-set! ht 1 2)
  (check (ht 1) => 2))

(let* ((mod10 (lambda (x) (modulo x 10)))
       (digit=? (lambda (x y) (= (modulo x 10) (modulo y 10))))
       (comp (make-comparator number? digit=? #f mod10))
       (ht (make-hash-table comp)))
  (hash-table-set! ht 1 2)
  (hash-table-set! ht 11 3)
  (check (ht 1) => 3)
  (check (ht 11) => 3)
  (check (ht 21) => 3)))
```

△ 4 ▽

hash-table [索引]
alist->hash-table [索引]

goldfish/srfi/srfi-125.scm

```
(define alist->hash-table
  (typed-lambda ((lst list?))
    (when (odd? (length lst))
      (value-error "The length of lst must be even!"))
    (let1 ht (make-hash-table)
      (let loop ((rest lst))
        (if (null? rest)
            ht
            (begin
              (hash-table-set! ht (car rest) (cadr rest))
              (loop (cdr rest))))))))
```

△ 5 ▽

14.4.3 谓词

hash-table? (obj) => boolean?

S7内置函数。判断一个对象是不是哈希表。

hash-table-contains? ((ht hash-table?) key) => boolean?

实现

goldfish/srfi/srfi-125.scm

```
(define (hash-table-contains? ht key)
  (not (not (hash-table-ref ht key))))
```

△ 6 ▽

测试

```
tests/goldfish/liii/hash-table-test.scm
(let1 ht (make-hash-table)
  (hash-table-set! ht 'brand 'liii)
  (check (hash-table-contains? ht 'brand) => #t)
  (hash-table-set! ht 'brand #f)
  (check (hash-table-contains? ht 'brand) => #f))
```

hash-table-empty? [索引] ((ht hash-table?) => boolean?)

实现

```
goldfish/srfi/srfi-125.scm
(define (hash-table-empty? ht)
  (zero? (hash-table-size ht)))
```

测试

```
tests/goldfish/liii/hash-table-test.scm
(check (hash-table-empty? empty-ht) => #t)
```

```
(let1 test-ht (make-hash-table)
  (hash-table-set! test-ht 'key 'value)
  (check (hash-table-empty? test-ht) => #f))
```

hash-table=? [索引] ((ht1 hash-table?) (ht2 hash-table?) => boolean?)

[改进实现，需要使用typed-lambda保证ht1和ht2都是哈希表]

实现

```
goldfish/srfi/srfi-125.scm
(define (hash-table=? ht1 ht2)
  (equal? ht1 ht2))
```

测试

```
tests/goldfish/liii/hash-table-test.scm
(let ((empty-h1 (make-hash-table))
      (empty-h2 (make-hash-table)))
  (check (hash-table=? empty-h1 empty-h2) => #t))

(let ((t1 (make-hash-table))
      (t2 (make-hash-table)))
  (hash-table-set! t1 'a 1)
  (hash-table-set! t2 'a 1)
  (check (hash-table=? t1 t2) => #t)
  (hash-table-set! t1 'b 2)
  (check (hash-table=? t1 t2) => #f))
```

14.4.4 选择器

hash-table-ref [索引] ((ht hash-table?) key) => value

ht. 哈希表

key. 键

value. 返回hash表中key这个键对应的值

SRFI 125定义的`hash-table-ref`的函数签名是这样的：`(hash-table-ref hash-table key [failure [success]])`。两参数形式的`hash-table-ref`是S7 Scheme的内置函数。

在S7 Scheme中，可以直接将hash-table视作一个单参数的函数，比如`(ht 'key)`等价于`(hash-table-ref ht 'key)`。

tests/goldfish/liii/hash-table-test.scm △ 8 ▽

```
(check (hash-table-ref empty-ht 'key) => #f)

(let1 ht (make-hash-table)
  (hash-table-set! ht 'key 'value)
  (check (hash-table-ref ht 'key) => 'value)
  (check (ht 'key) => 'value))
```

hash-table-ref/default [(ht hash-table?) key default] => value
[需要设计一种合理的方式，标注default参数实际上是惰性求值的]

ht. 哈希表**key.** 键

default. 默认值，如果key这个键在哈希表中对应的值不存在，则返回默认值。注意，该默认值只有在key这个键不存在的时候，才会被求值。

value. 键对应的值，如果不存在，则为默认值。

测试

当键对应的值存在时，default不会被求值，故而测试中的`(display "hello")`实际不会被执行。

tests/goldfish/liii/hash-table-test.scm △ 9 ▽

```

17.4 Base64编解码介绍

Base64编码是一种将任意字节序列编码为可打印字符的方式，其编码和解码的过程如下：

编码的长度计算：

Base64的编码长度与输入数据的长度相关，长度计算公式为：

$$\text{length(output)} = \left\lceil \frac{\text{length(input)}}{3} \right\rceil \times 4$$

其中，输入的每3个字节被转换为4个Base64字符。如果输入的字节数不是3的倍数，会在编码后用=符号填充，保证输出长度始终是4的倍数。

输入数据的分组与填充：

表格 17.1. 最后一组不足的元素需要设置为#f [table:16.1]

b1	b2	b3
0-255	0-255	0-255
0-255	0-255	#f
0-255	#f	#f

输入的字节流被分为每组3个字节进行编码。对于不足3个字节的最后一组，根据不同情况补充#f（表示填充字节）。表格 17.1展示了3种情况：

- 如果有3个字节，则正常处理。
- 如果有2个字节，则第三个字节补充为#f。
- 如果只有1个字节，则后两个字节补充为#f。

映射规则：

每组3个字节 $[b_1, b_2, b_3]$ 将映射为4个Base64字符 $[c_1, c_2, c_3, c_4]$ ，其中，Base64字符的取值范围是字母、数字、+、/，以及可能的填充符号=。映射的具体规则如下：

- 将3个字节（24位）按6位一组，分成4个部分，每个部分对应一个Base64字符。
- 如果不足3个字节（即有填充的情况），则最后一个或两个Base64字符会用=替代。

例子：

假设输入为"Man"，其ASCII值为77, 97, 110，其二进制表示为：

77 = 01001101, 97 = 01100001, 110 = 01101110

将24位二进制分为4组，每组6位：

010011, 010110, 000101, 101110

转换为Base64字符，分别对应T, W, F, u。因此，“Man”的Base64编码为TWFu。

解码时，过程反过来：将Base64字符转换为6位二进制，再拼接回原始的字节序列。

Base64编码的特点是保持输入的可读性并使其适合传输，但相较于原始数据，会增加大约33%的大小。

```

19.2 接口

在Scheme语言中，`case-lambda`是一种特殊的lambda表达式，它可以根据不同数量的参数执行不同的代码块。`case-lambda`允许你定义一个函数，这个函数根据传入参数的数量来选择执行不同的lambda表达式。

下面是一个使用`case-lambda`的示例：

```
tests/goldfish/scheme/case-lambda-test.scm
(import (liii list)
        (liii check)
        (scheme case-lambda))

(check-set-mode! 'report-failed)

(define (my-func . args)
  (case-lambda
    ((()) "zero\u208bargs")
    ((x) (+ x x))
    ((x y) (+ x y))
    ((x y . rest) (reduce + 0 (cons x (cons y rest))))))

(check ((my-func)) => "zero\u208bargs")
(check ((my-func) 2) => 4)
(check ((my-func) 3 4) => 7)
(check ((my-func) 1 2 3 4) => 10)

(check-report)
```

19.3 实现

```
goldfish/scheme/case-lambda.scm
; 0-clause BSD
; Bill Schottstaedt
; from S7 source repo: r7rs.scm

(define-library (scheme case-lambda)
  (export case-lambda)
  (begin

;; case-lambda
(define-macro (case-lambda . choices)
  '(lambda args
    (case (length args)
      ,@(map (lambda (choice)
                (if (or (symbol? (car choice))
                        (negative? (length (car choice))))
                    '(else (apply (lambda ,(car choice) ,@(cdr choice)) args))
                    '(((length (car choice)))
                      (apply (lambda ,(car choice) ,@(cdr choice)) args))))
                choices)))))

) ; end of begin
) ; end of define-library

//
```

23.2 入口

金鱼Scheme的入口是非常精简的，主要的逻辑在[src/goldfish.hpp](#)里面。这样做的好处在于方便复用hpp文件中的源代码。

```
src/goldfish.cpp
#include "goldfish.hpp"

int
main (int argc, char** argv) {
    return goldfish::repl_for_community_edition (argc, argv);
}
```

23.3 实现

头文件

```
src/goldfish.hpp
#include <algorithm>
#include <cstdlib>
#include <iostream>
#include <s7.h>
#include <string>
#include <vector>

#include <tbox/platform/file.h>
#include <tbox/platform/path.h>
#include <tbox/tbox.h>

#ifndef TB_CONFIG_OS_WINDOWS
#include <io.h>
#include <windows.h>
#else
#include <pwd.h>
#include <unistd.h>
#endif

#if !defined(TB_CONFIG_OS_WINDOWS)
#include <errno.h>
#include <wordexp.h>
#endif
```

GOLDFISH_VERSION

金鱼Scheme的版本，[后续统一使用17.10.9这个在导言区预定义的值]。文学编程的Build Buffer功能暂时不支持展开导言区预定义的值。

```
src/goldfish.hpp
#define GOLDFISH_VERSION "17.10.9"
```

GOLDFISH_PATH_MAXN

```
src/goldfish.hpp
#define GOLDFISH_PATH_MAXN TB_PATH_MAXN
```

    glue_liii_os (sc);
    glue_liii_uuid (sc);
}
```

23.3.2 命令行

显示帮助

[src/goldfish.hpp](#)

△ 34 ▽

```
static void
display_help () {
    cout << "GoldfishScheme" << GOLDFISH_VERSION << " by LiiiLabs" << endl;
    cout << "--version\t"
        << "Display version" << endl;
    cout << "-m default\t"
        << "Allowed mode: default, liii, sicp, r7rs, s7" << endl;
    cout << "-e \t"
        << "Load the scheme code on the command line" << endl
        << "\t\teg. -e (begin (display 'Hello) (+ 1 2))" << endl;
    cout << "-l FILE\t"
        << "Load the scheme code on path" << endl;
    cout << "FILE\t"
        << "Load the scheme code on path and print the evaluated result" << endl;
}
```

显示版本

[src/goldfish.hpp](#)

△ 35 ▽

```
static void
display_version () {
    cout << "GoldfishScheme" << GOLDFISH_VERSION << " by LiiiLabs" << endl;
    cout << "based on S7 Scheme" << S7_VERSION << "(" << S7_DATE << ")" << endl;
}
```

错误的命令行选项

[src/goldfish.hpp](#)

△ 36 ▽

```
static void
display_for_invalid_options () {
    cerr << "Invalid command line options!" << endl << endl;
    display_help ();
}
```

执行文件中的代码

```
src/goldfish.hpp
static void
goldfish_eval_file (s7_scheme* sc, string path, bool quiet) {
    s7_pointer result= s7_load (sc, path.c_str ());
    if (!result) {
        cerr << "Failed to load" << path << endl;
        exit (-1);
    }
    if (!quiet) {
        cout << path << "=" << s7_object_to_c_string (sc, result) << endl;
    }
}
```

执行命令行中以字符串形式传入的代码

```
src/goldfish.hpp
static void
goldfish_eval_code (s7_scheme* sc, string code) {
    s7_pointer x= s7_eval_c_string (sc, code.c_str ());
    cout << s7_object_to_c_string (sc, x) << endl;
}
```

金鱼Scheme的初始化

1. 初始化S7 Scheme
2. 为S7 Scheme设置load path
3. 初始化tbox
4. 初始化胶水代码

```
src/goldfish.hpp
s7_scheme*
init_goldfish_scheme (const char* gf_lib) {
    s7_scheme* sc= s7_init ();
    s7_add_to_load_path (sc, gf_lib);

    if (!tb_init (tb_null, tb_null)) exit (-1);

    glue_for_community_edition (sc);
    return sc;
}
```

金鱼Scheme的运行模式

-m帮助您指定预加载的标准库。

default. -m default等价于-m liii

liii. 预加载(liii base)和(liii error)的金鱼Scheme

sicp. 预加载(`srfi sicp`)和(`scheme base`)的S7 Scheme

r7rs. 预加载(`scheme base`)的S7 Scheme

s7. 无任何加载库的S7 Scheme

`src/goldfish.hpp`
